DEAL, supposed to have been the *Dola* of Julius Cæsar, is a market and seaport town of England, in the hundred of Bensborough, lathe of St Augustine, and county of Kent. It is situated on the sea-coast opposite the Downs, which being a general rendezvous for all kinds of shipping, has contributed greatly to the prosperity of Deal. The coast is here bold and open, and by an extensive bank of beach stones and pebbles thrown up by the waves, the sea has defended the coast from its own violence. The town is composed chiefly of three streets, which are parallel to the coast, and are joined by others smaller and narrower. In the upper part of the town, the streets are broad and spacious, but in the lower part of it, they are narrow and dirty. The houses are chiefly built of brick, and are very irregular, but those which have been recently erected are more elegant and commodious. Besides the parish church, which is at a distance from the town, there is a chapel of ease in the lower town, which was erected about the beginning of the last century. It is built of brick, and is 80 feet by 50 in the inside. The roof is of timber, curiously framed, and wholly supported on the side walls. The castle, which consists chiefly of a round tower, for the accommodation of a small garrison, stands to the south of the town, has a drawbridge, and is surrounded by a deep ditch; but Deal is principally defended by the batteries and martello towers which were recently built on the adjacent eminences. The other public buildings are a regular custom-house, a naval storehouse, an extensive naval hospital, a public library, and a reading-room. Extensive barracks have also been erected near the castle.

The inhabitants are principally occupied in maritime operations. There is here a regular establishment of 49 pilots, for the safe conveyance of shipping from and to the Downs, and up the rivers Medway and Thames. The charges are regulated by the tonnage; and it is a privilege of the pilots of the upper book, (or those who have been longest on the list,) to pilot all ships that draw more than 11 feet 4 inches of water. By their intrepidity, and that of the *Hovellers*, or sailors who assist them, much valuable property, and many valuable lives, have been preserved in cases of shipwreck. Two markets are held here weekly, and two fairs annually. East Long. 1° 23′ 59″, and North Lat. 51° 13′ 5″.

The following is an abstract of the population return in 1811, for the parish.

Inhabited houses,	1,340
Families that occupy them,	1,582
Do. employed in agriculture,	25
Do. in trade and manufacture,	156
Do. not included in these classes,	1,401
Males,	3,382
Females,	3,969
Total population in 1811,	7,351

See Hasted's *History of Kent*; and Brayley's *Beauties of England and Wales*, vol. viii. p. 1019—1024. (*j*)

DEATH. See PHYSIOLOGY.

DEBRETZIN, DEBREZEN, a large and populous town of Austria, in Upper Hungary. This town is of the most wretched description. The streets are not paved, and in those which are most frequented, balks are laid down in the middle for the accommodation of foot passengers. The town is surrounded with a hedge, and the gates, which are like our common field gates, are stuck with thorns and brambles. The houses, which are thatched, have generally only one story, and have their gable ends towards the street. The Calvinists, who form the majority of the inhabitants, have a college, which is numerously attended; but the buildings are old and ruinous. The *Togati*, who alone live in the college, amount to 400. Eight of them are lodged in one room. The younger scholars, who are nearly one thousand in number, live out of the college. The library is filled with the classics and scholastic divinity.

One of the principal manufactures here is soap, which gives employment to 70 master boilers, and is made from natron, a natural mineral alkali, called szekso. It is an efflorescence, which is found on a sandy soil at a lake near Kismaria, only a few miles from Debretzin. The soap is sent to every part of Hungary. There is likewise a manufactory of woollen stuff resembling a sheep's skin, called *guba*, and another of pipes. There is an imperial saltpetre manufactory near the town, and also a few vineyards. About 1000 cwt. of saltpetre is annually sent from Debretzin to the Imperial Magazine at Cashaw; but only 200 cwt. of it is produced here. The rest is received in the impure state, and is only purified. Horned cattle are reared in great abundance in the neighbourhood. The inhabitants are obliged to go more than a quarter of a mile for water. Population 30,000. See Townson's *Travels in Hungary*, p. 238—249. (*w*)

DEBT, NATIONAL, is the name for the amount, accumulated in a course of years, of government expence above revenue. In former ages, the extent of the sum in hand constituted, in a great measure, the limit of the public outlay. Our ancestors, though equally desirous with us of augmenting their expenditure, had little conception of the method of obtaining temporary loans, and none whatever of making permanent ones, by forming their collective amount into a transferable stock. It was to the thought and ingenuity of the Italians, that Europe has to attribute this, along with many other discoveries. That reflecting people found out, that the way to give a value to a sum of debt, where the security was fair, however slow the progress of payment, was to convert the whole into a disposable property. The power of transferring shares from one individual to another, was thus rendered a kind of counterpoise to the want of present solvency on the part of the government; and it was found to be enough that government performed punctually the duty of paying the interest.

It was at the æra of the Revolution that this innovation first took place in our financial system. The public confidence in the new government, the establishment of freedom on a solid basis, and the ardour to repress the endless encroachments of Louis XIV. all combined to give stability to a plan, which would have sunk in a moment to the ground under the arbitrary sway of a James or a Charles. These considerations gave support to the system during the doubtful, and sometimes unsuccessful, contest, which was terminated by the peace of Ryswick. Notwithstanding a considerable reduction in the interval between that treaty and the death of King William, the funded debt of the country amounted, in 1701, to 16,000,000; and many grave politicians considered twenty millions as a ruinous point in the progress of accumulation.

After the peace of Utrecht, the attempts to discharge the national debt were made very gradually and feebly. A sinking fund, on a plan by no means unlike that of Mr Pitt, was established; but its operation was so slow, and so frequently interrupted, that the total discharge in the 27 years of peace, preceding the war of 1740, did not exceed L. 7,000,000 sterling. Queen Anne's war had carried the national debt to L. 50,000,000, and ministers finding that the country had been brought to bear the pressure of this load, were in no haste to attempt its alleviation: an attempt alone would it have been; for it is vain to talk of relieving the public from a burden contracted in the shape of debt, by war expences. The only mode of relief, as we shall shew more fully under the head of SINKING FUND, is by the imposition of fresh taxes; that is, by taking annually a sum out of our pockets to pay the interest, and eventually the capital of former arrears. This, in whatever way we view it, is little else than the transfer of a fund from one purpose to another; so that the sums expended in war may be clearly set down as so much absolute loss.*

At the peace of Aix-la-Chapelle, our debt was between seventy and eighty millions. The brilliant successes of the war of 1756, encouraging government to apply to Parliament for extravagant sums, the result was the accumulation of our debt, before the peace of 1763, to more than one hundred and twenty millions. The American war carried it above two hundred millions; and the war of 1793 made it more than double that amount. In these enumerations we are desirous to represent the sums, not in stock, but in sterling money; a calculation frequently attended with complexity, on account of the difficulty of reducing the various descriptions of stock to a sterling sum, by which we mean a sum bearing the regular legal interest of five per cent. In the present war, expensive as it has been beyond all precedent, and, we may add, beyond all conception, the addition to our debt has been comparatively inconsiderable. The extraordinary amount of our war taxes, and of the produce of the sinking fund, have formed powerful grounds of counteraction, to the infinite satisfaction of those well-intentioned persons who persuade themselves that the extraction of money from the capital of individuals, in the shape of taxes, is a less pernicious thing than the accumulation of public debt.

The following Table represents the gradual progress of our national debt till a late period. The sums are given, not in sterling money but in stock, and the debt of Ireland is not included.

Amount of the National Funded Debt at the Revolution, and at the commencement and termination of each subsequent War.

		Years.	Stock.
National debt at the Revolution,		1689,	L. 1,054,925
Funded debt at the peace of Ryswick,		1697,	21,515,772
.... at the commencement of the war of		1701,	16,394,701
.... at the peace of Utrecht,		1714,	55,282,978
.... at the commencement of the war,		1740,	47,954,623
.... at the peace of Aix la Chapelle,		1748,	79,193,313
.... at the commencement of the war,		1756,	73,289,673
.... at the peace of Paris,		1763,	133,959,270
.... at the commencement of the American war,		1775,	123,644,500
.... at the peace of Versailles,		1783,	238,231,248
And this was reduced by purchases for the redemption of the national debt, at the commencement of the war, to		1793,	227,989,148
Funded debt at the peace of Amiens 1802, including the loan of that year,	L. 567,008,978		
Of which redeemed, and in the hands of the commissioners for the reduction of national debt,	67,255,915		
		Leaves	499,753,063
There was no reduction of the national debt in the short peace which followed the treaty of Amiens.			
Funded debt 1st February 1812,	L. 769,764,356		
Of which redeemed,	189,538,480		
		Leaves	580,225,876

It may be useful to compare the progressive increase in the annual ratio of our contracted debt, in the successive wars since the Revolution. During the war of 1689, the annual average of debt contracted was two millions and a half, and in Queen Anne's war three millions. In the war of 1740 it was somewhat below four millions; and under the flattering successes of the contest of 1756, government found means to carry its annual augmentations to more than eight millions and a half. In our unfortunate contest with our colonies, the yearly average of addition to our debt was fourteen millions; and in the war of 1793, when our hopes were raised by a concurrence of circumstances, it exceeded thirty millions; a sum of surprising magnitude, when we add to it the farther burden imposed on the people for the payment of the taxes appropriated to the sinking fund. It is fit, however, to add, that these sums are calculated in stock. Of the sterling amount, a more accurate idea will be formed from the following Table.

Progress of the Funded Debt of Britain from 1793 to 1812.

Years.		Sterling Money.
1793	Loan	£4,500,000
1794	Loan	11,000,000
	Navy Bills	1,907,451
1795	Loan	18,000,000
	Navy Bills	1,499,647
	Loan	18,000,000
1796	Loan	7,000,000
	Navy Bills	4,226,727
	Loyalty Loan	18,000,000
1797	Loan	13,000,000
	Navy and Exchequer Bills,	13,029,399
1798	Loan	15,000,000
	Loan	3,000,000
1799	Loan	12,500,000
1800	Loan	18,500,000
	Carry over	£159,163,224

* The important subject of the Sinking Fund has been discussed in a most profound and perspicuous manner, by Dr R. Hamilton, in his "Inquiry concerning the Rise and Progress, the Redemption and Present State, and the Management of the National Debt of Great Britain." Edin. 1813. ED.

	Brought forward . . .	£159,163,224
1801	Loan	25,500,000
1802	Exchequer Bills	8,910,450
	Loan	23,000,000
1803	Loan	10,000,000
1804	Loan	10,000,000
1805	Loan	20,000,000
1806	Loan	18,000,000
1807	Loan	12,200,000
1808	Loan	8,000,000
	Exchequer Bills	4,000,000
1809	Loan	11,000,000
	Exchequer Bills	7,932,100
1810	Exchequer Bills	8,311,000
	Loan	8,000,000
1811	Exchequer Bills	7,018,700
	Loan	4,981,300
	Loan	12,000,000
		£356,854,673

Ireland dates the origin of her public debt at an epoch greatly posterior to that of Britain. It did not, indeed, exceed a few millions until the war of 1793, in the course of which it advanced with a rapidity almost as great, making allowance for the striking disproportion of funds, as the arrears of Britain. The sums borrowed were partly on the security of Ireland alone, but more on the joint security of Ireland and Britain. Of the latter, the following Table exhibits a list.

Loans for Ireland guaranteed by Britain.

1797	. . . .	L. 1,500,000
1798	. . . .	2,000,000
1799	. . . .	3,000,000
1800	. . . .	2,000,000
1801	. . . .	2,500,000
1802	. . . .	2,000,000
1803	. . . .	2,000,000
1804	. . . .	4,500,000
1805	. . . .	2,500,000
	Separate loan	1,500,000
1806	. . . .	2,000,000
1807	. . . .	2,000,000
	Separate loan	1,500,000
1808	. . . .	2,500,000
1809	. . . .	3,000,000
1810	. . . .	4,000,000
	Separate loan	1,400,000
		L.39,900,000

Reducing the various descriptions of British debt, funded and unfunded, to one general sum, and estimating the amount of that sum by the interest which government is pledged to pay, we shall find that in the present year our annual interest has risen, one way or another, to nearly thirty millions sterling. Multiplying this sum by twenty, on the assumption of five per cent. being the regular interest of money, we make a gross sum of six hundred millions sterling. This sum, large as it appears, will probably be found below the mark, because in the event of peace, 3 and 4 per cent. stocks may take a value not very remote from that of L. 100 in money. Applying a similar rule to the case of Ireland, we shall carry the amount of her debt to nearly eighty millions sterling, being somewhat less than a seventh of our own.

In examining the operation of our sinking funds prior to 1793, we cannot fail to be struck with the insignificance of its proportion to the general mass of our debt. In the long peace between 1714 and 1740, the average annual re-payment was only a two hundredth part of the whole. Again, in the pacific interval from 1763 to 1775, the ratio, though somewhat better, was still below the one hundred and thirtieth part of the capital; and between 1783 and 1793, it became less than ever, for it did not exceed a two hundred and twentieth part. The trifling proportion of these sums to the whole, seems to amount to a demonstration, that so long as wars are of frequent recurrence, the hope of paying off any considerable part of the national debt is a delusion. Each contest sinks us deeper and deeper into difficulty, and tends to create a suspicion that ministers have not been serious in their promises of extensive liquidation. In treating of the article SINKING-FUND, we shall take occasion to shew that this boasted engine is fitter to extract additional sums from the pockets of the people, than to operate a reduction of prior incumbrances. Farther explanations, in connection with this subject, will be given under the several heads of LOAN, LONG ANNUITY, LOTTERY, and TONTINE. The practical result of these different statements will be, that the calculations of extraordinary benefit, from the operation of compound interest, are unfounded, and that the only effectual source of reduction consists in the excess of revenue above expenditure.

We conclude by a Table explanatory of the progressive advance of our revenue from a very remote period. The inaccuracy and ambiguity of ancient records, prevent it from possessing a claim to the character of official accuracy; but it is notwithstanding curious as an approximation to a fair statement of the amount of the public income at various periods.

Computed amount of the Public Revenue at the commencement of each Reign.

	Years.	Sterling Money.
William the Conqueror, .	1066	L.400,000
William Rufus, ...	1087	350,000

1808	Annual produce of the sinking fund,	10,000,000
	Free revenue,	L.35,224,110

(χ)

DECAMERIDE, in Music, is an interval so named by M. Sauveur, who considered the octave as divided into 43 merides, each of these into 7 heptamerides, and each of these again into 10 decamerides, or the $\frac{1}{3010}$th part of the octave, which was done, to make the same conform nearly to the four first places of the reciprocal logarithms of VIII, and so that one in the fourth place of such reciprocal common logarithms may very nearly represent a decameride, which, as $\frac{1}{3010}\times$ VIII, has a common logarithm of .9998999,9003 = .2040574 Σ, whereas 9999000,0000 is the common log. and .2040370 Σ the value in Farey's notation of 1 in the fourth place of reciprocal logarithms. The decameride is =.0185374 in major comma logs. and =.000332226 in Euler's, or binary logs. or decimals of the VIII. (ϱ)

DECASPORA, a genus of plants of the class Pentandria, and order Monogynia. See Brown's *Prodromus*, &c. p. 548, and BOTANY, p. 174.

DECCAN, a general term signifying the *south*, and applied by the Hindoos to that immense tract of country lying to the south of the river Nerbudda. By some modern geographers it has been arbitrarily restricted, merely for their own convenience, to that part of India which lies to the south of the river Kistna, and its subsidiary streams. See CANARA, CARNATIC, INDIA, &c. (*j*)

DECIMALS. See ARITHMETIC, Vol. II. p. 395—403.

DECLINATION. See ASTRONOMY, Vol. III. p. 608.

DECOSTEA, a genus of plants of the class Diœcia, and order Pentandria. See BOTANY, p. 340.

DECUMARIA, a genus of plants of the class Dodecandria, and order Monogynia. See BOTANY, p. 224.

DECUPLE SCHISMA, in Music, is an interval equal to 10 schismas, or $9.992138\Sigma+m$; its common logarithm being .9950989.2767, its Euler's log. .0162810, and its comma log. .9084418. The *decuple minor comma* is $99.708541\Sigma+2f+9m$; the *decuple major comma* is $109.700678\Sigma+2f+10m$; the *decuple diaschisma* is $119.7006782+2f+10m$, &c. (ϱ)

DEDICATION. See CONSECRATION.

DEERINGIA, a genus of plants of the class Pentandria, and order Monogynia. See Brown's *Prodromus Plant. Nov. Holl.* p. 413, and BOTANY, p. 172.

DEFECTIVE INTERVALS, in Music, are such as are less than their true quantity; but with different authors this flattening differs. Some use the term for intervals less by the schisma, (or Σ,) others by the minor comma, (or $10\Sigma+m$,) the diaschisma, (or $12\Sigma+m$,) the enharmonic diesis, (or $21\Sigma+2m$,) and others again by the semitone minimum, (or $32\Sigma+3m$.)

DEFECTIVE SCALES, in Music, are such as are incapable, for want of a sufficient number of notes in an octave, of avoiding the use of *wolves*, occasioned by the substitution of one note for a different one which ought to be used. See *Philosophical Magazine*, vol. xxxvi. p. 39. All douzeaves are therefore defective, except perhaps the isotonic system, which some maintain to be made up entirely of wolves. Dr Robert Smith proposed, as a mode of tuning the common defective scale of 12 notes, that each fifth should be made to *beat* equally quick with the major third, to the same base, the former *flat*, and the latter *sharp*, except the resulting fifth between G ✻ and E♭. In his "Harmonics," 2d edit. p. 215, the *beats* of this system are calculated; and in the *Philosophical Magazine*, vol. xxxvi. p. 50, Mr Farey has given its temperaments. (ϱ)

DEFICIENT INTERVALS, in Music, in the nomenclature which we have adopted in our work, are such as are flatter than the true intervals by a major *comma* c, $(=11\Sigma+m)$. Sometimes these are called *comma-deficient* intervals. Double deficient intervals are lessened $2c$ $(=22\Sigma+2m.)$ Mr Holder, and some other writers, will be found to have used this prefix in different senses. His deficient less third, for instance, is $\frac{6}{7}$=3rd $-24.9476962\Sigma+f+2m$, instead of $3-c$. (ϱ)

DEFOE, or FOE, DANIEL, an English author of considerable eminence, was the son of James Foe, a citizen of London, and was born in London, it is believed, about the year 1663. His family being dissenters, he was educated at a dissenting academy, kept by Charles Morton at Newington Green. He is said to have followed, for some time, the profession of a hosier; but possessing little of the talents and attention requisite for the management of business, he was soon compelled to relinquish it, and thereafter devoted himself almost exclusively to literature and politics.

In the year 1683, before he had attained the age of twenty-one, he published a pamphlet against the prevailing sentiment in favour of the Turks, as opposed to the Austrians; and before the age of twenty-three, he joined the standard of the Duke of Monmouth, in 1685. Having escaped the dangers of war, and the fangs of legal prosecution, he found leisure to pursue his literary career, and was prompted by his zeal to mingle in the controversies of the reign of James II. whose government he efficaciously opposed.

Defoe was admitted a livery-man of London on the 26th of January 1687-8. At the period of the revolution, when, in consequence of the popular discontents, King William was obliged to dismiss his Dutch guards, Defoe, who possessed just notions on the subject of civil liberty, wrote his well known poem, *The True-born Englishman*, with the view of casting ridicule upon those who opposed the government. This production was well received by the public, and met with an almost unparalleled sale; it was also the means of introducing him to the person of King William, for whose favours the author always expressed his gratitude. In the year 1695, he was appointed accountant to the commissioners for managing the duties on glass, which office, however, fell when the commission was abolished by the suppression of the tax in 1699.

The death of William deprived Defoe of a patron and protector. During the furious party contests which ensued on the accession of Queen Anne, he took an active part in the discussion of the various political and religious questions which were then agitated; and his zeal drew upon him the resentment of the individuals in power. In the month of January 1702-3, a proclamation was issued, offering a reward of fifty pounds for discovering his retreat. In this proclamation he is charged with writing " a scandalous and seditious pamphlet, entitled, *The shortest way with the Dissenters*," an ironical production, which he gave to the world towards the end of the year 1702; and in the Gazette he is described as " a middle-sized spare man, about forty years old, of a brown complexion, and dark-brown coloured hair, but wears a wig, a hooked nose, a sharp chin, grey eyes, and a large mole near his mouth." It was to no purpose that Defoe published " An Explanation:" he was found guilty of a libel, sentenced to the pillory, and adjudged to be fined and imprisoned. The author, however, appears to have been so little affected by the ignominious part of his punishment, that he consoled himself, when in prison, by writing a hymn to the pillory. In the solitude of a gaol, he occupied himself in correcting for the press a collection of his writings, aud projected " The Review," a periodical paper, which was first published on the 19th of February 1703-4.

While he lay in the prison of Newgate, as he tells us, without hopes of deliverance, a verbal message was brought him from Sir Robert Harley, the Speaker of the House of Commons, desiring to know what he could do for him: to which Defoe answered by writing the story of the blind man in the gospel, concluding—*Lord, that I may receive my sight.* Harley became secretary of state in the month of April 1704; and by his interposition, the author was at length relieved from Newgate, in the month of August of the same year. Immediately after his deliverance, he retired to St Edmund's Bury, and continued his satirical productions, for which he was liable to occasional persecution.

In the year 1706, Defoe was called upon to engage in business of more importance. Lord Godolphin resolved to take the benefit of his talents in promoting the union with Scotland, and, with this view, introduced him to the queen, who expressed herself towards him in very flattering terms. In three days thereafter he was sent to Scotland; and he arrived at Edinburgh in the month of October. Here he zealously employed his pen in confuting the arguments urged by the opponents of the great measure which was then in agitation; and he attended the committees of Parliament, for whose use he made several of the calculations on the subject of trade and taxation. On the 16th of January following, the act of Union was passed by the Parliament of Scotland; and Defoe returned to London in February 1706-7. After his first benefactor, Harley, was driven from power, in 1707, Lord Godolphin still patronised him, and he continued to contribute his services to the government.

In the year 1709, Defoe published his *History of the Union*; a work which was little noticed on its first appearance, but which was republished in 1712, and a third time in 1786. In the same year he also published *The History of Addresses;* and in 1711, he gave a second volume of Addresses, with serious and comical remarks. Upon the change of ministry, in 1710, he was again thrown back upon his first benefactor, and by his means preserved his interest with the government. He now lived at Newington, in comfortable circumstances, occasionally publishing such tracts as his prejudices or necessities dictated.

On the 1st of February, 1710–11, the corporation of the city of Edinburgh, remembering the services which Defoe had rendered to Scotland, empowered him to publish the *Edinburgh Courant,* in the room of Adam Booge; though it does not appear probable that he continued long to act in the capacity of editor of that paper. He was then engaged, at a distance, in business of a more important nature, supporting Lord Oxford's South Sea project, by his *Essay on the South Sea Trade,* and publishing other tracts relative to the political measures of the day. Although an advocate for peace, he wrote against the treaty of Utrecht, conceiving that its terms were prejudicial to the commercial interests of this country. In the month of May 1713, he discontinued the *Review,* after having published it regularly during nine years; and commenced the publication of a *General History of Trade,* in monthly numbers, of which only two appeared. In these factious times he was compelled to seek personal safety in retirement. The place of his retreat is believed to have been Halifax, or the borders of Lancashire. At this period he published several pamphlets in favour of the Hanover succession; for which, however, he was arrested, obliged to give eight hundred pounds bail, and prosecuted by information, during Trinity term 1713. In Easter term of the same year he was committed to Newgate; but was soon released, upon making a proper submission; and his first benefactor, who was still in power, procured him the Queen's pardon in the month of November. When the Earl of Oxford was finally expelled from administration, it is probable that our author lost his original appointment; and upon the accession of George I. notwithstanding his services in support of the Protestant succession, he was discountenanced even by those who had derived benefit from his exertions.

In consequence of the persecutions and disappointments which he had so frequently experienced, Defoe seems now to have become weary of party writing, and began to turn his attention towards other subjects. In the year 1715, he published *The Family Instructor,* a useful work, which, although little noticed on its first publication, at length met with a general reception. To this work he afterwards added a second volume; and in 1722, he published his *Religious Courtship.* In the month of April 1719, he gave to the world the *Life and surprising Adventures of Robinson Crusoe,* the most popular of all his performances, of which the reception was immediate and universal. It has often been said, that Defoe had surreptitiously appropriated the papers of Alexander Selkirk, a Scottish sailor, who had been left ashore on the island of Juan Fernandez, in the South Sea, and had lived upon that desolate place for about four years, until he was at length relieved by Captain Woodes Rogers, in his voyage round the world. From this charge, however, the author of *Robinson Crusoe* is, we think, successfully vindicated by Mr Chalmers; and the fact is, that Selkirk's story had been already told in Woodes Rogers's voyage, published in 1712.

From this period, Defoe continued to employ his pen upon a variety of publications, the most remarkable of which are, *The Life and Piracies of Captain Singleton,* 1720; *the History of Moll Flanders,* 1721; *the Memoirs of a Cavalier,* which appear to have been published without a date; and *the Political History of the Devil,* 1726. To these may be added several works on trade and commerce, which are now little read. After a life so constantly and assiduously employed in literary pursuits, Defoe died, at an advanced age, in the month of April, 1731. Few authors have left behind them so great a variety of publications; and although many of the works of Defoe have long ceased to be perused with interest, there are some of his productions which will probably continue to be re-published and read so long as the English language endures.

The reader will find a long list of the numerous works of Defoe, annexed to Mr Chalmers's Life of the Author, published at the end of Stockdale's edition of *Robinson Crusoe*, London, 1790. (z)

DEGREE. See Astronomy, Geography, and Surveying *Trigonometrical.*

DEGUELIA, a genus of plants of the class Diadelphia, and order Decandria. See Botany, p. 285.

DELAGOA Bay, is a bay on the east coast of Africa, and is called by the Portuguese the bay of Lorenzo Marques, after the name of its discoverer, and likewise the bay of the Holy Ghost. It extends about 20 leagues from north to south, and 7 from east to west; but on account of the numerous shoals, the channel is not more than five miles broad. At the north point of the bay, or Cape St Mary's, is formed an island of the same name, separated by a rocky strait from the continent.

The chief rivers that run into the bay, are the Manica, the Machavanna, and Delagoa, or English River. The Manica, which is the most northern of the three, was discovered in 1545 by the Portuguese. Being at that time navigable for large vessels, they erected a fort, which is now in ruins; but from the accumulation of sand at the mouth of the river, they were obliged to abandon their settlement.

The Machavanna, which is the most southern of the rivers, is navigable to the place where the trade is carried on, within 30 leagues from its mouth, by boats that draw six feet of water.

The Delagoa, or English River, which lies between the other two, is distant about 8 leagues from the Machavanna river, and is navigable for nearly 200 miles by large boats, and for more than 40 miles by vessels that draw 12 feet of water. It has a bar, with about 15 feet on it at low water; and about 2 miles up the river there is a sufficient depth of water, where vessels generally lie in safety from every wind. The Dutch fort and factory were destroyed in 1727 by a squadron of English pirates. The Austrian, or Ostend East India Company, erected warehouses, and a battery of 12 guns, on the south side of the river, in 1777; but in consequence of a remonstrance from the court of Portugal, the Austrian government disavowed the settlement, and the ships and effects of the settlers were seized and carried off by the Portuguese. It is now principally frequented by English South Sea whalers, from the quantity of whales which are found in the bay. The Portuguese carry on an inconsiderable trade with the natives, and send annually a ship from Mozambique, and sometimes return with slaves. The Persees on the Malabar coast, occasionally send small vessels to Delagoa bay with piece goods, cutlery, wearing apparel, iron, copper, brass wire, buttons, Arrangoe beads, pipes, sugar, spirits, and tobacco, and receive in return elephants' teeth, the teeth of the hippopotamus, a little ambergris, and small quantities of gold dust.

The chief who resides at the village where the ships anchor, has about fourteen chiefs on the south side of the river subject to him, and reigns over a territory extending about 200 miles inland, and about 100 along the coast. The houses, which are circular, are about 15 feet in diameter, and are very neat. They have only one entrance, and are encircled with pallisadoes about four feet high. The soil is of a rich black mould, and is sown with rice or maize in the months of December or January. The dry season generally continues from April till October. Vegetables and fruit, but particularly the sugar cane, are raised in abundance; but there are no horses, asses, or buffaloes. The wild animals which are found here, are the tiger, the rhinoceros, antelope, hare, rabbit, wild hog; and there are also Guinea hens, quails, partridges, wild geese, and ducks. The natives are of a bright black colour. They are harmless and good-natured, but are very cunning in their dealings with strangers. Those on the north side of the river are great beggars, and those who live up the river, are more traitorous and cruel than those who live near the bay.

As soon as a vessel arrives, an officer, who is called the king of the water, gives information of it to the chief, who instantly comes down to the landing-place. After presenting him with liquor and old clothes, he gives a bullock in return; and by the aid of the king of the water, provisions and refreshments may be procured every day in great plenty, and at a reasonable price. A bullock of 3 or 4 cwt. may be obtained for a piece of coarse Surat piece goods. Fowls may be had for two metal buttons or an iron hoop each, and empty bottles, and old clothes, will readily procure vegetables and fruits of all kinds. Excellent fish of various kinds are to be had at a small rate, and sometimes turtle is obtained. Water and firewood also abound. Mr White supposes, that the inhabitants in the neighbourhood of the bay may amount to from six to ten thousand. Cape St Mary's, which is the north-east point of the island of the same name, is situated in east longitude 33° 15′, and in north latitude 25° 58′. See White's *Journal of a Voyage from Madras* 1800, and Milburn's valuable work on *Oriental Commerce,* vol. i. p. 56, 57. (π)

DELAWARE, the smallest of the united states of America, is bounded on the east by the Atlantic Ocean and by the river and bay of the same name, on the south by the parallel of 38° 29′ 30″, on the west by Maryland, and on the north by the territorial circle described, with a radius of 12 miles round the town of Newcastle, by which it is divided from Pennsylvania. This state, which derives its name from Lord De la War, is about 92 miles in its greatest length, and from 13 to 30 miles in breadth, and is divided into three counties, Newcastle, Kent, and Sussex, the first of which pays 8 parts, the second 7, and the third 6 parts of the taxes.

The general aspect of this state is that of an extended plain, favourable for cultivation. Some of the upper parts of the county of Newcastle indeed, are broken and irregular. The heights of Christiana are lofty and commanding, and the hills of Brandywine are rough and stony; but in the lower country there is very little diversity of level. The highest ridge of the peninsula runs through the state of Delaware, inclined to the eastern side, and is marked out by a chain of swamps, from which a number of waters descend on the west to the Chesapeake, and on the east to the river Delaware. Along the Delaware river, and about 9

Delaware.

miles into the interior, the soil is commonly a rich clay, which produces large timber, and is well adapted to the purposes of agriculture; but between this tract and the swamps, the soil is light, sandy, and of an inferior quality. In the county of Newcastle, the soil is a strong clay. In Kent it is mixed with sand, and in Sussex the sand greatly predominates. The productions of the soil are wheat, Indian corn, barley, rye, oats, flax, buck wheat, and potatoes. The wheat is held in the highest estimation, from its uncommon softness and whiteness, and is always preferred in the foreign markets. In the county of Sussex there are excellent grazing lands; and it exports great quantities of timber, obtained from the Cypress Swamp or Indian River, which extends about 6 miles from east to west, and nearly 12 from north to south, including an area of 50,000 acres.

The state of Delaware supplies Philadelphia with its staple commodity. No less than 265,000 barrels of flour, 300,000 bushels of wheat, 170,000 bushels of Indian corn, besides oats, barley, flax seed, paper, flat iron, snuff, and salted provisions, &c. are annually exported from the waters of the Delaware state. The following was the amount of exports from 1791 to 1796 inclusive:

Years.	Dollars.	Cents.
1791	119,878	93
1792	133,972	27
1793	93,559	45
1794	207,985	33
1795	158,041	21
1796	201,142	
1801	440,504	

Wheat being the staple commodity of this state, large establishments have been erected for manufacturing it into flour. Of these, the mills in the Brandywine are most worthy of notice; but as they are within half a mile of WILMINGTON, they will be described with more propriety under that article. There are also well constructed mills on Red Clay and White Clay creeks, and on other streams in different parts of the state.

The state of Delaware contains very few minerals. In the county of Sussex, and among the branches of the Nanticoke River, are large quantities of bog iron ore, well adapted for casting. Before the revolution it was wrought to a great extent, but since that event the business has greatly declined.

The Presbyterians are the most numerous and powerful sect in the state of Delaware, and have no fewer than 24 churches; the Episcopalians have 14; the Anabaptists 7; and there is a great number of Quakers and Methodists in the state, but particularly in the counties of Kent and Sussex.

The principal river in the state is the Delaware, or *Chihohocki*, as it was called by the natives. The rivers Pocomoke, Wicomico, Nanticoke, Choptank, Chester, Sassafras, and Bohemia, rise in the western parts of the state, and discharge their waters into Chesapeake Bay. Some of them are navigable about 25 miles up the country, by vessels of about 55 tons. Delaware bay is about 60 miles long, from the Cape to the mouth of the river at Bombay Hook, and is in some parts so wide, that a ship in the middle of it is invisible from the land. The river rises in two branches in the state of New York; the northernmost, called Mohawks, or Cockquago branch, having its origin in Lake Ustayantho, in Lat. 42° 25′. The bay and river are navigable for 155 miles up to the great or lower falls at Trenton, and a 74 gun-ship may go up to Philadelphia, which is 120 miles from the sea. Sloops are able to go 35 miles above Philadelphia to Trenton Falls. Boats of 9 tons can go 135 miles above that city, and Indian canoes 185 miles above it.

Delft, Delhi.

The state of Delaware was colonized by the Swedes in 1628, and constituted a part of New Sweden, now New Jersey. It was taken by the Dutch in 1656, and was afterwards subdued in 1683 by the Duke of York, who sold to William Penn the town of Newcastle, and 12 miles of the surrounding country. To this tract he afterwards added the county which extends as far as Cape Henlopen, divided it into three counties as at present, and added it to Pennsylvania. In 1701, he sold it to six individuals, who having obtained for it the privilege of a separate assembly, it took the name of the three counties of the Delaware. These three counties separated themselves at the revolution from Pennsylvania, and assumed the name of the state of the Delaware.

The population in 1790 was 50,097, of whom 8887 were slaves. More recently, the population has been estimated at 64,273, of whom 6153 are slaves. See Morse's *American Gazetteer*, Rochefoucauld de Liancourt's *Travels in the United States of America*, vol. ii. p. 266; and the article WILMINGTON. (π)

DELFT, in Latin *Delphi*, a large and fine city of Holland, is situated on the river Schie, between Rotterdam and the Hague, in one of the finest districts of the country. The city is nearly two miles in circumference, and is defended from the sea by three dykes. The streets are long, straight, and spacious; the houses are very handsome and good, and the town is divided into several quarters by fine canals, planted on each side with trees. The principal public buildings are the town or guildhall, which is very magnificent; the arsenal and four powder magazines, which were formerly the best supplied in Holland. Besides the reformed Dutch church, there is a French church, a Lutheran church, and some others for the Roman Catholics. The two principal churches are adorned with the tombs of Admiral Tromp, Admiral Piel Heyn, and the celebrated naturalist Leewenhoek. The superb monument erected to William of Nassau, shewing his faithful dog lying at his feet, is particularly worthy of notice. The palace is still shewn, where this prince was assassinated in 1584. Delft has been long celebrated for its earthen ware, which is manufactured in imitation of the porcelain of China and Japan. It is made of baked earth, covered with an enamel. Fine and coarse cloths are also manufactured here; and M. Cauzius has lately established a manufactory of instruments of physics, astronomy, and surgery. Distance from the Hague four miles. Population 22,200. (π)

DELHI, one of the soubahs or provinces of Hindostan, is bounded on the east by Agrah, on the west by Lahore, south by Agimere, and north by the Kummow hills. Its length, from the town of Pulwul, near Agrah, to the river Sutluz, is 160 coses; its breadth is 140 coses, from the Kummow hills to the town of Rewari. Delhi, once of considerable extent and importance, is now a very miserable province. Ravaged for more than half a century by incessant wars, its boundaries have been greatly circumscribed; many of its towns have been destroyed; and its fine country, formerly swarming with inhabitants, and teeming with the richest vegetable productions, now presents only scenes of gloomy desolation. Wheat, rice, sugar, indigo, millet, pulse, and fruits of various kinds, are the almost spontaneous productions of its fertile soil. No part of Hindostan enjoys a climate of so mild a temperature; yet its wretched inhabitants, groaning under the most grievous oppression, and in constant dread of being pillaged, have, for many years, scarcely dared to rear for themselves the means of a scanty subsistence. We fervently hope, that, under the milder influence of the British jurisdiction, which now extends to Delhi, confidence and industry will revive; and that the people will reap all the advantages which nature has placed within their reach. This province is now divided into eight circars or districts, namely, Shahjehanabad, Serhind, Hissar, Feiroozeh, Schaurunpore, Sumbal, Bedaoon, Narnoul. These are again subdivided into 289 inferior districts, yielding, according to the imperial register, a revenue of seventy-four crore, sixty-three lacks of dams, equivalent to L.1,850,000 sterling. (*k*)

DELHI, the chief town of the above province, was once the capital of Mussulman sovereignty in Hindostan, and at a remoter period, the seat of Hindu dominion over northern India. It is said, by some historians, to have been founded by Rajah Delu, who reigned in Hindostan prior to the invasion of Alexander the Great. Others ascribe its erection to Rajah Pettouvar, who flourished at a much later period. Its name in Sanscrit is Indraput, or the abode of Indra, one of the Hindu deities; and it is thus distinguished in the royal diplomas of the chancery office. It is first mentioned as the capital of Hindostan about the year 1200. Rising in importance as Canouge declined, it continued the unrivalled capital of India till the year 1398, when it was reduced, almost without a battle, by the resistless Tamerlane. It was on the month of December in that year, that this stern conqueror entered the city, planted on its walls the great standard of the Tartarian empire, and seated in all the pride of conquest on the throne of India, received the prostrate homage of the nobility of both nations. The wanton insolence, and the cruel ravages of the conquerors, having at length roused the inhabitants to resistance, Delhi, with all its fine monuments of art, was devoted to pillage; and, on the 13th of January, this imperial city was reduced to a heap of ruins. Under succeeding sovereigns, however, it recovered part of its former splendour, and was still accounted the capital of Hindostan, till Akbar, transferring the seat of royalty to Agra, towards the close of the sixteenth century, completed the destruction of Delhi. Of the ruins of this once superb city, the extent is not less than a circumference of twenty miles; and the environs to the north and south are crowded with the remains of spacious gardens and country houses of the nobility.

About the year 1631, Shah Jehan, grandson of Akbar, with the view of eternizing his memory, founded a town near the ruins of old Delhi, which received the name of Shah Jehan Abad, or the colony of Shah Jehan. By this name the modern Delhi continues till this day to be distinguished in Hindostan. It is situated in a champaigne country, on the western bank of the Jumna, a river, says Bernier, resembling the Loire. It is about seven miles in circumference; and, except on the side next the river, is surrounded by a wall of brick and stone. A parapet runs along the whole, but there are no cannon planted on the ramparts. The seven gates of the city, called the Lahore gate, Delhi gate, Agimere gate, Turkoman gate, Moor gate, Cabul gate, Cashmere gate, are built of stone, and have handsome arched entrances, where the guards of the city keep watch. The fortress, containing the Mahal or Seraglio, and other royal apartments, stands between the town and the river; from which it was separated by an area of considerable extent, where elephants used to be exercised, and where the militia of the Omrahs and Rajahs were frequently mustered before the king, who reviewed them from the windows of one of his apartments. The walls of the fortress were encompassed, except towards the river, by a ditch lined with freestone. Around this ditch was a spacious garden, beyond which was the great street, the *place royal*, where were erected the tents of the rajahs, who held there alternately their weekly guard. At the entrance to the palace, when Bernier wrote his description of it, were two stone figures, representing the rajah of Chittore and his brother Potta, seated on two elephants. These figures were afterwards removed by order of Aurengzebe, as tending to favour idolatry; and the place, on which they stood, he enclosed with a screen of red stone, which has very much disfigured the entrance. After entering the palace, the first object that attracts attention is the *Dewaun Aum*, or public hall of audience, a noble edifice, situated at the upper end of a spacious square. All round the square are apartments of two stories in height, the walls and front of which, while the empire retained its splendour, were richly adorned with tapestry, velvets, and silks, the rajahs and omrahs vying with each other in the magnificence of their decorations. A handsome gateway leads from the Dewaun Aum to the Dewaun Khass, situated likewise at the upper end of a spacious square, elevated upon a terrass of marble about four feet in height. This edifice, which is 150 feet in length by 40 in breadth, was, in better days, adorned with wonderful magnificence; and, though repeatedly despoiled by successive invaders, still retains sufficient splendour to excite admiration. The roof is flat, supported by numerous columns of fine white marble, which have been richly ornamented with inlaid flower-work of different coloured stones: The corners and borders have been decorated with frieze and sculptured work. The ceiling was formerly incrusted, through its whole extent, with a rich foliage of silver, which has long since been taken away. In the compartments of the walls the inlaying is exquisitely delicate. Around the exterior of the building, in the cornice, is an inscription in letters of gold, upon a ground of white marble, to the following effect: "If there be a paradise upon earth, this is it,—'tis this—'tis this." The terrace of this building is composed of large slabs of white marble, and on the top are four pavilions, or cupolas, of the same materials. A little to the northward of the Dewaun Khass are the royal baths, built by the Emperor Shah Jehan. They consist of three very large rooms, surmounted by domes of white marble. The walls within are lined with marble, about two-thirds of their height, having beautiful borders of flowers, worked cornelians, and other stones, executed with much taste. The floors are paved with marble in large slabs. From fountains in the centre, the water is conveyed by pipes to the different apartments; and large reservoirs of marble, four feet in depth, are placed in the walls. The light is admitted from the roof by windows of stained glass; and capacious stoves, with iron-gratings, are placed underneath each separate apartment. Adjoining to the baths is a very fine mosque. In the royal gardens is a very large octagon room, lined with marble, which faces the Jumna: It was through the window of this room that the late heir-apparent, Mirza Juwaun Bukht, made his escape in 1784, when he fled to Lucknow. Great part of the palace has been destroyed by the late invaders; the Rohillas, in particular, have stripped many of the rooms of their marble ornaments and pavements. The fort of Selim Ghur communicates with the palace by a bridge of stone built over an arm of the river: it is now entirely in ruins.

The royal gardens, begun in the fourth year of the reign of Shah Jehan, and finished in the thirteenth, were laid out with admirable taste, and are said to have cost the enormous sum of a million sterling. These gardens contained the *Dewaun Khana*, or hall of audience; an *Ivaun*, or open hall, with apartments adjoining, the interior of which is decorated with a beautiful border of white and gold painting, upon a ground of the finest *chunam;* on each side of the Ivaun are the apartments of the haram inclosed by high walls. These gardens, about a mile in circumference, still abound with trees of a large size, and very old.

Delhi contains the remains of many splendid palaces belonging formerly to the great Omrahs of the empire. The plans of all these palaces are nearly the same. All of them are surrounded by high walls, and take up a considerable space of ground. The entrances to all of them are through lofty arched gateways, at the top of which are the galleries for music; and before each is a spacious court-yard for the elephants, horses, and attendants of the visitors. Each has a Mahal, or seraglio, separated by a partition-wall from the great hall, with which it communicates by means of private passages. All of them had gardens, with capacious reservoirs of stone, and fountains in the centre. Round each palace extended an ample terrace; and within the walls were houses and apartments for servants and followers, besides stabling for horses, elephants, and every thing appertaining to a nobleman's suite. Each palace was likewise provided with a handsome set of baths, and a Teh Khana under ground.

The environs of Delhi to the north and west are crowded with remains of spacious gardens and country houses of the nobility, which were abundantly supplied with water by means of a canal dug by Ali Merdan Khan, and which formerly entered from above the city of Panniput down to Delhi, where it joined the Jumna, fertilizing a tract of more than nine miles. There was another aqueduct at Delhi, begun by order of Feeroze Shah, to supply with water a hunting seat at Sufedoom. This canal, which conveyed the water from Khizinabad, where it left the Jumna, was about sixty miles long, and was continued sixty miles more, by Shan Jehan, to his new capital of Delhi. These canals are now choked up with rubbish, to the great sorrow of the inhabitants, whose incessant prayer is that they may be cleared by the liberality of the British government.

This city is adorned with many beautiful mosques, the most remarkable of which is the *Jama Musjid*, or great cathedral. This elegant structure stands about a quarter of a mile from the Royal Palace, upon a rocky eminence, scarped on purpose. Four long and fine streets corresponding to the four sides of the mosque, terminate in the terrace on which it is built. This terrace is a square of about 1400 yards of red-stone; in the centre is a fountain lined with marble, for enabling the votaries to perform the necessary ablutions before prayer. The ascent is by a flight of stone steps, thirty-five in number, through a handsome gateway of red-stone. The large doors of this gateway are covered with plates of brass, exquisitely wrought. An arched colonnade of red-stone surrounds the terrace, which is adorned with octagon pavilions. The mosque is of an oblong form, two hundred and sixty-one feet in length; it is surrounded at the top by three magnificent domes of white marble, intersected with black stripes, and flanked by two minarets of black marble and red stone alternately, rising to the height of 130 feet. Each of these minarets has three projecting galleries of white marble, and their summits are crowned with light octagon pavilions of the same. The whole front of the building is faced with large slabs of beautiful white marble; and along the cornice are ten compartments, each four feet long, and two and a half wide, inlaid with inscriptions in black marble, and said to contain the greater part, if not the whole of the Koran. The floor of the mosque is paved with large slabs of white marble, decorated with a black border; its walls and roof are lined with plain white marble. Near the Kibla * is a handsome Taak, or niche, adorned with a profusion of frieze work; and close to this is a Mimber, or pulpit, of marble, which has an ascent of four steps balustraded. The ascent to the minarets is by a winding staircase of 130 steps of red stone; and at the top, the spectator is gratified by a noble view of the city, and of the opposite bank of the Jumna. The domes are crowned with cullises of copper richly gilt. This superb edifice, worthy of being the great cathedral of the empire of Hindostaun, was begun by the Emperor Shah Jehan, in the fourth year of his reign, and completed in the tenth: The expence of its erection is said to have amounted to ten lacks of rupees. The other mosques worthy of mention, are the Roshun Al Dowla, from which Nadir Shah beheld the massacre of the unfortunate inhabitants; and Zeenut Al Musajid, or the ornament of mosques, erected by Zeenut Al Nissa, a daughter of Aurengzebe. In a corner of the terrace on which this mosque is situated, that princess caused a sepulchre of white marble to be built, in which she was interred in the year of the Hegira 1122, (A. D. 1710). Besides these mosques, there are in Delhi and its environs above forty others, inferior in size and beauty, though all built in a similar style.

The other objects in Delhi which attract attention, are the Mudirussa, or college, erected by Gazoodeen Cawn, now uninhabited; and the tombs of Malika Zemani, queen of the Emperor Mahmud Shah, and of Jehanarah Begum, eldest daughter of the Emperor Shah Jehan—a princess no less famous for her wit, gallantry, and beauty, than for the noble proof which she gave of filial attachment, in undergoing a voluntary confinement of ten years with her father in the castle of Agrah.

From the account of these splendid structures, our readers are not to imagine, that Delhi presents an appearance of uniform magnificence. Here, as in all the Indian cities, the streets are narrow and irregular; and the houses, built without order, of brick, mud, or bamboos and mats, and generally covered with thatch, resemble a motley group of villages, rather than an extensive town. In Delhi, indeed, there were formerly two very noble streets, the one leading from the palace gate through the city to the Delhi gate, in a direction north and south; the other entering in the same manner, from the palace to the Lahore gate, lying east and west. The inhabitants have spoiled the beauty of both these streets, by running a line of houses down the centre, and in other places across the street, so that it is difficult to discover their former position.

* The Kibla is a small excavation in the wall of Mahommedan mosques, so situated as to look towards the city of Mecca.

In the better days of this city, Bernier supposed its population to be nearly equal to that of Paris. In the time of Shah Jehan, its yearly revenue amounted to L. 3,125,000. During the reign of Aurengzebe, (the third son of Shah Jehan,) who mounted the throne in 1659, the revenue of the city amounted to 1,221,950,137 dams, or L. 3,818,594; and its population was computed at two millions. It continued to increase in splendour and importance till the invasion of Nadir Shah, who demanded 30 millions sterling by way of ransom. It was on this occasion that 100,000 of the inhabitants were massacred, and 62 millions of plunder were said to have been collected. This unhappy city was again pillaged and depopulated in 1756, 1759, and 1760, by Ahmed Abdallah. Shah-Aulum, the lineal descendant of the house of Timoor, aspiring to the throne of his ancestors, put himself into the hands of the Mahrattas, who promised to support him in his enterprise. The distresses of this deluded prince compelled him at length to depute his son, in 1784, to solicit the assistance of the English. Since the peace of 1782, Madajæ Scindia, a Mahratta chief, and possessor of the principal part of Maliva, has taken the lead at Delhi, and has been endeavouring to extend his conquests on the side of Agimere, with the view of establishing a considerable kingdom. By these successive invasions and ravages, the opulence and population of Delhi have been greatly reduced, and are necessarily so fluctuating and precarious, that they cannot be exactly ascertained. North Lat. 28° 36′, East Long. 77° 40′. See Bernier's *Memoirs concerning the Empire of the Great Mogul,* vol. ii. Franklin's *History of the Reign of Shah-Aulum,* Appendix i. *Asiatic Researches,* vol. iv. (*k*)

DELOS. There are two islands situated in the mouth of the Greek Archipelago, called *Dili, Sidili,* or Great and Little Delos, which were particularly celebrated among the ancients, by the name of *Rhenæa,* and *Delos.* It is chiefly to the latter, as the more noted, that our attention shall here be directed.

Delos was celebrated neither for its size nor productions, being only seven or eight miles in circuit, and covered with a barren soil; but from its fame in the mysteries of Pagan mythology, it was considered of far greater importance than a rich and extensive sovereignty. According to fabulous story, when Latona, pregnant by Jupiter, was persecuted by Juno, Neptune raised the island from the bottom of the sea by a blow of his trident, in order to afford her a place of refuge; and it is said to have derived its name, signifying *to appear,* from the mode in which it was produced. Nevertheless, according to other traditions, the island long floated at the will of the waves, until Neptune fixed it to receive Latona, who was there delivered of twins, Apollo and Diana. Herodotus examined Delos in the course of his travels, and declares that it did not float; but some of the moderns have written dissertations to prove, that such might have been the case, without any violation of the law of nature.

This island was consecrated in a special manner to Apollo and Diana, who each derived a name from Mount Cynthus, a hill upon it; and some of the other heathen divinities had also temples there. It contained wealthy and populous cities, and its inhabitants, held in veneration as servants of the gods, were, by an Athenian decree, entitled to a golden crown in the festivals of Minerva. There was a magnificent temple dedicated to Apollo, which was erected by the united labours of all the Grecian potentates, who likewise jointly contributed to its preservation in suitable splendour. Plutarch informs us, that there was an altar in it deemed one of the wonders of the world, from the admirable art with which it was constructed; yet it consisted of nothing more than the horns of goats killed by Diana on Mount Cynthus, which were twisted into the proper form without glue or nails. Here there was a colossal marble statue of Apollo twenty-four feet high, presented by the inhabitants of the island of Naxos, now mutilated and in fragments; but the pedestal, a huge block of polished marble, and dedicatory inscriptions, yet remains. As Latona suckled her offspring under a palm tree, a brazen one, of great size, was erected beside the temple by Nicias, an Athenian general, which the ancients relate was overthrown on the statue by a tempest. The chief temple of Apollo was founded above 1500 years before Christ. Adrian, the Roman emperor, built two temples dedicated to Neptune and Hercules, and also a city called New Athens. The oracular responses to the credulous are reported to have been less mysterious in Delos than those delivered from the other fanes of Apollo.

All the surrounding nations, and some at a remote distance, concurred in celebrating the honours of the Delian divinities: hostilities were then laid aside, and mutual enemies might repair in safety to the island. Theseus, in commemoration of his escape from the Minotaur in Crete, instituted a divine legation, which was scrupulously preserved by the Athenians; and during its absence, or that of other deputations, no criminal could be put to death in their city. This legation, called the *Theory,* bore a crown of gold for Apollo, numerous victims for sacrifice, priests, and choirs of virgins to perform the sacred rites. An ancient inscription on marble, brought to Britain by the Earl of Sandwich in the earlier part of the preceding century, tends to elucidate this part of Pagan mythology. Its date remounts to about 374 years before the Christian æra, and it shows the expences lavished on superstitious offerings by the devotees of that period. The sums due to the temple of Delos, both by individuals and the Grecian states, are there enumerated, as well as the price of the golden crown for the god; of 109 oxen for sacrifice, paid to the captain of the galleys bearing the legation, and the remuneration of the archtheorist, who was at its head. On the arrival of the Theory, the statue of Apollo was crowned, and the victims offered; then dancing around the altars by young Athenians, representing the motions of the island while floating on the waves, commenced, in which the Delian females soon mixed, to figure the mazes of the Cretan labyrinth, whence Theseus returned in safety. Games, and competitions in poetry, likewise took place; and the Athenians instituted horse racing as a part of the former. The landing of the Theory having been irregularly conducted previous to the age of Nicias, when he was appointed arch-theorist, he carried the priests, choir, victims, and other preparations to the neighbouring island of Rhenæa, and cast a bridge five or six hundred yards long, richly ornamented with gold paintings and carpets, all made at Athens, over the intermediate channel to Delos. Thus, instead of the priests and choirs promiscuously hurrying from the vessels, and having taken their crowns and vestments, beginning to sing in a disorderly manner, a solemn and magnificent procession was conducted into the island. The same Grecian appropriated certain revenues, to give an annual feast to the Delians, in order to propitiate the gods; and the terms of his donation were engraven on a marble pyramid.

Great numbers of Greeks, with their wives and families, now resorted to the island, either from religious motives, or to enjoy the festivals; and virgins arrived from the Hyperboreans, bearing the first fruits of their country. The site of that nation is not ascertained, but we learn that the rights of hospitality having been violated with respect to their deputies, they thenceforward employed an intermediate people to convey their offerings. The decease of two priestesses is commemorated, who were entombed at Rhenæa, or Great Delos; for it was considered inconsistent with the sanctity of the island that the dust of mortals should be mixed with its soil, or that any one should be born upon it. Women whose term of parturition approached, were therefore carried to Rhenea, and likewise dying persons: It appears, however, that there was some difficulty in the latter case; for we find successive ordinances for the purification of the island, by transporting all the dead bodies from it to Rhenea: and on one occasion of purification, the Athenians, to whom the island belonged, expelled the whole inhabitants. "How can you call Delos your native country," said a certain person to another, "seeing you could neither be born there, nor can you die on it?"

The great resort of strangers enriched the island; it was equally famed for wealth and merchandize, and the ancients called it the treasury and emporium of Greece. Cornelius Nepos, speaking of a contribution by the states, uses these words: *Quantum pecuniæ quæque civitas daret Aristides delectus est qui constitueret. Ejus arbitrio quadraginta et sexaginta talenta quotannis Delum sunt collata. Id enim commune ærarium esse voluerint.* Cicero, in one of his orations, calls Delos "an island whither all repair with cargoes and merchandize." And Strabo describes it as a great and opulent emporium, of such importance, that a proverb passed current, "Merchants freight a ship, dispatch her thither, and every thing is sold."

Delos, along with the revolutions of the surrounding state, declined from its ancient splendour; it experienced disasters, and was plundered of its riches, whence Pausanias, who lived in the second century of the Christian æra, records its decay: "Delos, which was formerly the emporium of Greece, is now so completely deserted, that if the sacred deputations of the Athenians were discontinued, the island would be almost destitute of people, counting Delians only."

It is now covered with ruins, among which the columns, altars, porticoes, and inscriptions, attest its former glory; but whether the destruction of its magnificent edifices resulted from the hands of men, or from the convulsions of the earth, so common in those regions, has not been preserved in history. The names of many distinguished characters of antiquity are disclosed among the fragments, such as Philip king of Macedon, Nicomedes Epiphanes king of Bithynia, Mithridates, and the like. The theatre, which, from an ancient inscription, appears to have been situated within the city of Delos, consisted of white marble, and is shewn by its remains to have been about 250 feet in diameter and 500 in circuit. Not far from the sea, are also the remains of the Naumachia, for naval exhibitions, an oval basin 289 feet in length by 200 in breadth, and 4 feet deep above the rubbish covering the bottom. The whole has been plastered with a very thick cement to confine the water, and it was encircled by a row of columns. Besides these, there are the ruins of a gymnasium, where competitions took place for prizes, which, to this day, is called "the schools," by the neighbouring islanders. The stream Inopus, exaggerated by the ancients as a river, is at present an inconsiderable brook rising from a fountain.

Delos is now totally deserted, except when occasionally the resort of pirates, who are said to murder navigators, and throw their bodies into the sea. Its ruins are likewise a copious store of materials, either for forming bullets for the unwieldy artillery of the Turks, or for being employed in other edifices by the inhabitants of the Archipelago.

Great Delos is an island considerably larger than the other, being fifteen or eighteen miles in circuit. The soil is said to be peculiarly adapted for the culture of vines and olives, and the Greeks of Myconi sow the most fertile parts with grain, and pasture some flocks upon it. Thus it is more favourable for population than *Little Delos,* which consists universally of schist or granite, and Mount Cynthus is entirely a hill of the latter. Though the history of the lesser island is the more celebrated, Great Delos appears, from the ruins with which it is covered, to have scarcely been inferior in splendour; and the tombs which are spoken of by the ancients still remain, some being of surprizing elegance. A Greek historian observes, that in his time most of them were occupied by the bodies of Carians and Phenicians, which was ascertained by their armour and the position wherein they lay. Tournefort counted 120 altars, which were chiefly cylindrical, and ornamented by sculptures.

The Knights of Malta had an establishment on Great Delos, which afterwards fell to decay, and the island is no longer inhabited. The inhabitants of Myconi pay a small revenue to the Turkish government for the privilege of occupying both for temporary uses. DELTA. See EGYPT.

DELUGE, in theology, signifies in general any great inundation; but more particularly that universal flood by which the whole inhabitants of this globe were destroyed, except Noah and his family. According to the most approved systems of chronology, this remarkable event happened in the year 1656 after the creation, or about 2348 before the Christian æra.

Of so general a calamity, from which only a single family of all who lived then on the face of the earth was preserved, we might naturally expect to find some memorials in the traditionary records of Pagan history, as well as in the sacred volume, where its peculiar cause, and the circumstances which attended it, are so distinctly and fully related. Its magnitude and singularity could scarcely fail to make an indelible impression on the minds of the survivors, which would be communicated from them to their children, and would not be easily effaced from the traditions even of their latest posterity. A deficiency in such traces of this awful event, though perhaps it might not serve entirely to invalidate our belief of its reality, would certainly tend considerably to weaken its claim to credibility; it being scarcely probable that the knowledge of it should be utterly lost to the rest of the world, and confined to the documents of the Jewish nation alone. What we might reasonably expect, has, accordingly, been actually and completely realised. The evidence which has been brought, from

Deluge.

almost every quarter of the world, to bear upon the reality of this event, is of the most conclusive and irresistible kind; and every investigation, whether etymological or historical, which has been made concerning heathen rites and traditions, has constantly added to its force, no less than to its extent.

And here, it were injustice to the memory of ingenuity and erudition, almost unexampled in modern times, were we not to mention the labours of Bryant, the learned annalist of *Ancient Mythology*, whose patience and profoundness of research have thrown such new and convincing light on this subject. Nor must we forget his ardent and successful disciple Mr Faber, who, in his *Dissertation on the Mysteries of the Cabiri*, has, in travelling over similar ground with his illustrious master, at once corrected some of his statements, and greatly strengthened his general conclusions. As the basis of their system, however, rests on a most extensive etymological examination of the names of the deities and other mythological personages worshipped and celebrated by the Heathen, compared with the varied traditions respecting their histories, and the nature of the rites and names of the places that were sacred to them, we cannot do more, in the present article, than shortly state the result of their investigations, referring for the particular details, to the highly original treatises already mentioned. According to them, the memory of the deluge was incorporated with almost every part of the Gentile mythology and worship: Noah, under a vast multitude of characters, being one of their first deities, to whom all the nations of the Heathen world looked up as their founder; and to some circumstance or other in whose history, and that of his sons and the first patriarchs, most, if not all, of their religious ceremonies may be considered as not indistinctly referring. Traces of these, neither vague nor obscure, they conceive to be found in the history and character, not only of Deucalion, but of Atlas, Cronus, or Saturn, Dionusos, Inachus, Janus, Minos, Zeus, and others among the Greeks; of Isis, Osiris, Sesostris, Oannes, Typhon, &c. among the Egyptians; of Dagon, Agruerus, Sydyk, &c. among the Phenicians; of Astarte, Derceto, &c. among the Assyrians; of Buddha, Menu, Vishnu, &c. among the Hindus; of Fohi, and a deity represented as "sitting upon the lotos in the midst of waters," among the Chinese; of Budo and Iakusi among the Japanese, &c. &c. They discover allusions to the ark, in many of the ancient mysteries, and traditions with respect to the dove and the rainbow, by which several of these allegorical personages were attended, which are not easily explicable, unless they be supposed to relate to the history of the deluge. By the celebrated Ogdoas of the Egyptians, consisting of eight persons sailing together in the sacred *baris* or ark, they imagine the family of Noah, which was precisely eight in number, to have been designated; and in the rites of Adonis or Thammuz, in particular, they point out many circumstances which seem to possess a distinct reference to the events recorded in the sixth and seventh chapters of Genesis. With regard to this system, we shall only further observe, that, after every reasonable deduction is made from it, which the exuberant indulgence of fancy occasionally exhibited by its authors appears to render necessary, it contains so much that is relevant and conclusive, that we cannot but express our conviction, that it has a solid foundation in truth and fact; it being scarcely possible to conceive, that a mere hypothesis could be supported by evidence so varied, so extensive, and in many particulars so demonstrative as that which its framers have produced.

Bryant's system.

Besides, however, the allusions to the deluge in the mythology and religious ceremonies of the Heathen, to which we have thus concisely adverted, there is a variety of traditions concerning it still more direct and circumstantial, the coincidence of which, with the narrative of Moses, it will require no common degree of sceptical hardihood to deny. These we shall now shortly adduce; beginning with those which are more distant and obscure, and then stating those which are more remarkably and circumstantially coincident with the Mosaic record.

Direct traditions.

We are informed by one of the circumnavigators of the world, who visited the remote island of Otaheite, that some of the inhabitants being asked concerning their origin, answered, that their supreme God having, a long time ago, been angry, dragged the earth through the sea, when their island was broken off and preserved.

In Otaheite,

In the island of Cuba, the people are said to believe, that "the world was once destroyed by water, by three persons," evidently alluding to the three sons of Noah. It is even related, that they have a tradition among them, that an old man knowing that the deluge was approaching, built a large ship, and went into it with a great number of animals; and that he sent out from the ship a crow, which did not immediately come back, staying to feed on the carcases of dead animals, but afterwards returned with a green branch in its mouth.

Cuba,

The author who gives the above account, likewise affirms, that it was reported by the inhabitants of Castella del Oro, in Terra Firma, that during a universal deluge, one man, with his children, were the only persons who escaped, by means of a canoe, and that from them the world was afterwards peopled.

Terra Firma,

According to the Peruvians, in consequence of a general inundation, occasioned by violent and continued rains, a universal destruction of the human species took place, a few persons only excepted, who escaped into caves on the tops of the mountains, into which they had previously conveyed a stock of provisions, and a number of live animals, lest when the waters abated, the whole race should have become extinct. Others of them affirm, that only six persons were saved, by means of a float or raft, and that from them all the inhabitants of the country are descended. They farther believe, that this event took place before there were any *incas* or kings among them, and when the country was extremely populous.

Peru,

The Brazilians not only preserve the tradition of a deluge, but believe that the whole race of mankind perished in it, except one man and his sister; or, according to others, two brothers with their wives, who were preserved by climbing the highest trees on their loftiest mountains; and who afterwards became the heads of two different nations. The memory of this event they are even said to celebrate in some of their religious anthems or songs.

Brazil,

Acosta, in his history of the Indies, says, that the Mexicans speak of a deluge in their country, by which all men were drowned; and that it was afterwards peopled by *Viracocha*, who came out of the lake Titicaca: and, according to Herrera, the Mechoachans, a people comparatively in the neighbourhood of Mexico, had a tradition, that a single family was formerly preserved in an ark amid a deluge of waters; and that along with them, a sufficient number of animals were saved to stock the new world. During the time that they were shut up in the ark, several ravens were sent out, one of which brought back the branch of a tree.

Mexico,

Deluge. Iroquois.

Among the Iroquois it is reported, that a certain spirit, called by them Otkon, was the creator of the world; and that another being called Messou, repaired it after a deluge, which happened in consequence of Otkon's dogs having one day when he was hunting with them lost themselves in a great lake, which, in consequence of this, overflowed in its banks, and in a short time covered the whole earth.

Oriental testimonies.

Passing from the more remote western to the eastern continent, nearer to the region where Noah is generally supposed to have lived, we find the traditions respecting the deluge still more particular and minute.

Josephus.

According to Josephus, there were a multitude of ancient authors, who concurred in asserting that the world had once been destroyed by a flood: "This deluge," says he, "and the ark, are mentioned by all who have written Barbaric histories, one of whom is Berosus the Chaldean. Speaking of this event, he affirms, that in Armenia, upon a mountain of the Corydeans, part of the ship is even yet remaining. It is a custom to scrape from off it some of the bitumen with which it was covered, and to carry it about as a talisman against diseases. Jerome the Egyptian, who wrote the ancient history of Phenicia, and Mnaseas, and many others, likewise mention these events. Nicolaus Damascenus relates, that there is a great mountain in Armenia, situated above Minyas, which is called *Baris,* to which many persons fled at the time of the deluge, and were preserved. One in particular was conveyed in an ark to the very summit of the mountain, and a considerable part of the vessel still remains. He perhaps may be the man concerning whom Moses the Jewish lawgiver wrote." Joseph. *Antiq. Jud.* lib. i. cap. 12.

Melo.

Eusebius (*Præp. Evang.* lib. ix. c. 19.) informs us, that Melo, a bitter enemy of the Jews, and whose testimony is on this account peculiarly valuable, takes notice of the person who was saved along with his sons from the flood, having been, after his preservation, driven away from Armenia, whence he retired to the mountainous parts of Syria. Abydenus, after giving an account of the deluge from which Xisuthrus, the Chaldean Noah, was saved, concludes with asserting, in exact concurrence with Berosus, that the ark first rested on the mountains of Armenia, and that its remains were used by the natives as a talisman. (Eusebii *Præp. Evang.* lib. i. c. 12.) And Plutarch (*de Solert. Animal.* v. ii.) mentions the Noachic dove, being sent out of the ark, and returning to it again, as an intimation to Deucalion that the storm had not yet ceased.

Chinese tradition.

This, however, is by no means all. Sir W. Jones, speaking of one of the Chinese fables, says, "Although I cannot insist with confidence, that the *rainbow* mentioned in it alludes to the Mosaic narrative of the flood, nor build any solid argument on the divine person Niu-va, of whose character, and even of whose sex, the historians of China speak very doubtfully; I may nevertheless assure you, after full inquiry and consideration, that the Chinese believe the earth to have been wholly covered with water, which, in works of undisputed authenticity, they describe as *flowing abundantly,* then *subsiding,* and *separating the higher from the lower age of mankind;* that the divisions of time, from which their poetical history begins, just preceded the appearance of Fo-hi, in the mountains of China; but that the great inundation in the reign of Yao, was either confined to the low lands of his kingdom, if the whole account of it be not a fable, or if it contains any allusion to the flood of Noah, has been ignorantly misplaced by the Chinese annalists." *Asiat. Research.* vol. ii. *Diss. on the Chinese.*

Egyptian.

The account given by Plutarch of the Egyptian Osiris, affords some grounds for imagining, that he also is the same person with Noah. He is said to have been a husbandman, a legislator, and a zealous advocate for the worship of the gods. Typhon having conspired against him, and, by a stratagem, having prevailed on him to enter into an ark, which was immediately closed on him, he, in this situation, floated down the Nile into the Sea. Now as, according to Plutarch, Typhon is merely a mythological person expressive of the ocean, this tradition evidently signifies nothing more than that the character denominated Osiris was in danger from the sea, and that he escaped by entering into an ark. Nor is it undeserving of notice, that he is said to have entered this vessel on the *seventeenth* of the month Athyr, which precisely agrees with the day of the patriarch's embarkation, previous to the commencement of the deluge. (*Plut. de Isid. et Osir.* p. 356, &c.) Plato also mentions, that a priest of Sais declared to Solon, that, previous to the partial deluges of Ogyges and Deucalion, a universal one had taken place, in which the original constitution of the earth was considerably altered. *Timæus,* p. 23. It is no doubt true, that Diodorus Siculus (*Bibl. Hist.* lib. i.) asserts, that the Egyptians maintained the flood of Deucalion to have been universal; but this discrepancy must appear, to every one who attends to the confusion which frequently pervades different accounts of the very same event, insufficient to invalidate the position, that the Egyptians *did* believe in a deluge that was universal.

Persian.

A similar belief prevailed among such of the ancient Persians as professed to hold their religion in its ancient purity, though some sects among them denied it entirely, and others maintained that it was only partial. Zoroaster is said to have affirmed, that such a catastrophe was occasioned by the wickedness and diabolic arts of a person called Malcûs; and, according to another of their authors, Noah himself dwelt in the mountain from which the waters of the deluge burst forth, though, by the same writer, an absurd tradition is mentioned of the particular place from which they issued: "*Zala-Cupha dicitur fuisse nomen vetulæ ex cujus furno aqua diluvii primo erupit.*" Hyde *de Relig. Vet. Pers.* c. x.

Chaldean.

Berosus, who lived in the time of Alexander, and wrote the history of the Babylonians, relates, that the general deluge happened in the days of king Xisuthrus, who, like Noah, was the *tenth* in descent from the first created man. Having in a dream been warned by Cronus or Saturn of the approaching calamity, he was commanded to build an immense ship, and embark in it with his wife, his children, and his friends; having first furnished it with provisions, and put into it a number both of birds and fourfooted animals. As soon as these preparations were completed, the flood commenced, and the whole world perished beneath its waters. After it began to abate, Xisuthrus sent out some of the birds, which, finding neither food nor resting-place, returned immediately to the ship. In the course of a few days he again let out the birds, but they came back to him having their feet covered with mud. The third time, however, that he sent them out, they returned no more. Concluding from this that the flood was decreasing, and the earth again appearing, he made an aperture in the side of the vessel, and perceived that it was approaching a mountain on which it, Deluge. soon after rested, when he disembarked with his family, adored the earth, built an altar, and sacrificed to the gods. Xisuthrus having suddenly disappeared, his family heard a voice in the air, which informed them, that the country in which they were was Armenia, and directed them to return to Babylon. *Syncelli Chronolog*. p. 30. Eusebii *Præp. Evang*. lib. ix. c. 12. and Joseph. *Antiq. Jud.*

Greek. Still more coincident even than this with the Mosaic account, is the Grecian history of the deluge, as preserved by Lucian, a native of Samosata on the Euphrates: and his authority is the more incontrovertible, on account of his being an avowed derider of all religions. The antediluvians, according to him, had gradually become so hardened and profligate, as to be guilty of every species of injustice. They paid no regard to the obligation of oaths; were insolent, inhospitable, and unmerciful. For this reason they were visited with an awful calamity. Suddenly the earth poured forth a vast quantity of water, the rain descended in torrents, the rivers overflowed their banks, and the sea rose to a prodigious height; so that "all things became water," and all men were destroyed, except Deucalion. He alone, for the sake of his prudence and piety, was reserved to a second generation. In obedience to a divine monition, he entered, with his sons and their wives, into a large ark, which he had built for their preservation; and immediately swine, and horses, and lions, and serpents, and all other animals which live on earth, came to him by pairs, and were admitted into the ark. There they became perfectly mild and innoxious, their natures being changed by the gods, who created such a friendship between them, that they all sailed peaceably together, so long as the waters prevailed over the surface of the globe. Lucian further adds, that, according to an ancient tradition at Hierapolis in Syria, there was once in that country a great chasm, through which the waters of the flood descended, and that Deucalion erected altars, and built a temple to Juno over its mouth. This aperture under the temple, he declares he had seen, thought it was then but of small size: and he relates a ceremony which took place twice every year, in memory of this catastrophe. Vessels full of water were brought from the sea, not only by the priests, but by the inhabitants of all Syria and Arabia; often attended also by multitudes from beyond the Euphrates. The water thus brought, was poured on the floor of the temple, and speedily sunk into the chasm; which, small as it was, received without difficulty the greatest quantity of water. And when they did this, the people said that "Deucalion himself had appointed it as a memorial of the deluge, and of his own deliverance from it." Lucian, *de Deâ Syriâ.*

Hindu. Scarcely less remarkable is the Hindoo tradition, with which we shall conclude this induction of testimonies to the reality of the deluge. It is contained in the ancient poem of the *Bhagavat*; and forms the subject of the first Purana, entitled Matsya, or the Fish. The following is Sir William Jones's abridgment of it, and the identity of the event which it describes, with that of the Hebrew historian, is too obvious to require any particular illustration. "The demon Hayagriva having purloined the Vedas from the custody of Brahma, while he was reposing at the close of the sixth Manwantara, *the whole race of men* became corrupt, *except the Seven Rishis,* and Satyavrata, who then reigned in Dravira, a maritime region to the south of Carnata. This prince was performing his ablutions in the river Critamala, when Vishnu appeared to him in the shape of a small fish, and after several augmentations of bulk in different waters, was placed by Satyavrata in the ocean, where he thus addressed his amazed votary: In seven days, all creatures who have offended me shall be destroyed by a deluge, but thou shalt be secured in a capacious vessel miraculously formed; take therefore all kinds of medicinal herbs, and esculent grain for food, and together with the seven holy men, your respective wives, and pairs of all animals, enter the ark without fear: then shalt thou know God face to face, and all thy questions shall be answered. Saying this, he disappeared; and after seven days, the ocean began to overflow the coasts, and the earth to be flooded by constant showers, when Satyavrata, meditating on the deity, saw a large vessel moving on the waters. He entered it, having in all respects conformed to the instructions of Vishnu; who in the form of a vast fish, suffered the vessel to be tied with a great sea serpent, as with a cable, to his measureless horn. When the deluge had ceased, Vishnu slew the demon, and recovered the Vedas, instructed Satyavrata in divine knowledge, and appointed him the seventh Menu, by the name of Vaivaswata." (*Asiat. Res.* vol. ii. on Chronol. of the Hindus.) And "according to the Pauranics, and the followers of Buddha," says Capt. Wilford, "the ark rested on the mountain of *Aryavarta, Aryawart,* or *India*; an appellation which has no small affinity with the *Ararat* of Scripture." *Ibid.* vol. vi. p. 521.

When we thus meet with some traditions of a deluge in almost every country, though the persons saved from it are said, in those various accounts, to have resided in different districts widely separated from each other, we are constrained to allow that such a general concurrence of belief could never have originated merely from accident. While the mind is in this situation, scripture comes forward, and presenting a narrative, more simple, better connected, and bearing an infinitely greater resemblance to authentic history, than any of those mythological accounts which occur in the traditions of Paganism, immediately flashes a conviction upon the understanding, that this must be the true history of those remarkable facts, which other nations have handed down to us, only through the medium of allegory and fable. By the evidence adduced in this article, indeed, the moral certainty of the Mosaic history of the flood appears to be established on a basis sufficiently firm to bid defiance to the cavils of scepticism. "Let the ingenuity of unbelief first account satisfactorily for this universal agreement of the Pagan world; and she may then, with a greater degree of plausibility, impeach the truth of the scriptural narrative of the deluge."

Besides the authorities already quoted, see Purchas's *Pilgrim*, b. ix. c. 5. 8. 10; Wilford *on Egypt; Asiat. Res.* vol. iii.; Maurice's *Indian Antiq.*; *Ancient Universal History*, vol. i.; Faber's *Horæ Mosaicæ*; and Cuvier's *Essay on the Theory of the Earth.* (*d*)

DELUGE, or Debacle, in Geology. Some writers have attempted to prove that traces of a deluge are apparent on the surface of the earth. Immense blocks of stone are found at a great distance from their native rocks; the bones of animals and the remains of plants, are found buried in regions far removed from what is supposed to be their native climate; and even in solid rock, both animal and vegetable substances abound, proclaiming mighty changes in the arrangement of the materials which compose the crust of the globe.

Disputes have arisen among philosophers respecting the reference of these appearances to a deluge, and the mode in which that agent might be brought into action by natural causes. We propose in a future article to enter pretty fully into the subject, when a greater number of facts shall have been collected and arranged. In the mean time, we are desirous of calling the attention of geologists to it by noticing, very shortly, the opinions of the few who have written any thing in this wide field of inquiry.

M. de Saussure, during his examination of the Alps of Switzerland, was forcibly struck with the appearance of blocks of granite, which had evidently belonged to the central ridge, lying scattered on the surrounding mountains and on the neighbouring valleys. To remove these blocks from their parent rock, and to transport them across deep and wide ravines, and over the summits of intervening mountains, seemed to require an agent of no ordinary power. The transportation of these blocks, Saussure ascribes to a vast torrent, which he imagined had, at a remote period, swept the earth, overtopping the Alps, and carrying masses of the rocks along with it. To this supposed torrent he applies the term *debacle*, a French word which is sometimes made use of to denote the clearing of a harbour, by setting at liberty a collection of water to sweep away the alluvial matter obstructing it. Our English word *deluge*, we consider more expressive of the extent of such a torrent as would be necessary to produce the effects in question.

While De Luc admits the *debacle* of Saussure, he ascribes the position of the blocks of granite to a cause which could have a place only in the most fantastic imagination, and which it is needless for us to detail. Neither of these philosophers appear to have digested their ideas of a deluge so perfectly, as to warrant their entering on any explanation of its cause, or even affording any precise idea of their notions respecting its operations when produced. Pallas, in his *Observations sur la formation des Montagnes*, ascribes the production of the deluge, which he supposes to have transported the remains of animals of one climate to another, to the action of volcanoes under the sea.

These speculations have remained almost unnoticed till lately, when Sir James Hall brought the subject before the Royal Society of Edinburgh, in a form more likely to attract attention. That gentleman has for many years been engaged in tracing what he conceives to be the effects of a powerful torrent, that has swept across Scotland from west to east. He has hitherto confined his researches to the vicinity of Edinburgh; and has accurately pointed out various places, where scratches and furrows on the surface of the rock are to be seen, and which are worthy of minute examination. These effects he ascribes to the attrition of the stones carried along by a deluge. Whoever examines the deep mass of gravel, sand, stones, and clay, which, in almost every country, covers the surface of the rock, acknowledges immediately that it has been deposited by water. But with respect to the manner in which the water operated, different opinions are entertained.

This subject does not seem to have been of sufficient importance to arrest the attention of the Wernerian school. The followers of Hutton are divided on this question; and while some of them assert, that the ordinary diurnal operations of the atmosphere and the action of rivers, are sufficient to account for all that has been observed, others maintain, that something more is required.

Sir James Hall appeals to the efforts of subterraneous heat acting under compression, as supposed by Dr Hutton, and endeavours to illustrate the mode in which he imagines a wave of sufficient magnitude to have been produced. We believe it to be now universally admitted, that concussions of the earth are occasioned by the exertion of an elastic fluid bursting the rocks which confine it. Sir James Hall supposes that such an exertion, by heaving up the superincumbent mass, and displacing a body of water, which is also impelled upwards by the concussion, would produce a wave on the surface of the sea. An earthquake felt on the coast, is commonly attended first with a retreat of the water from the shore; an effect which Sir James Hall accounts for, by the rising of the wave immediately above the place where the subterraneous force exerts itself. After this retreat, the water returns with great violence, and overwhelms every thing in its progress. These effects are illustrated by events during the earthquakes at Cadiz, Lisbon, and Callao. But the most remarkable, and the one which applies most strictly in illustration of Sir James Hall's ideas, is that related by Humboldt, of a large tract of ground, extending to three or four square miles, called the *Malpays*, in South America, having been raised, during an earthquake, to the height of 524 feet. This might have happened at the bottom of the sea, and there can be no doubt of similar events taking place in that situation.

Experiment has been resorted to by Sir James Hall; and by exploding gunpowder under water, he succeeded in producing in miniature, precisely the same effects which he supposed would arise from the concussion of an earthquake in the sea.

Having thus attempted to explain the means by which a vast wave, sufficient to overtop the mountains, might be raised, Sir James calls in the aid of glaciers, to assist in transporting large masses of stone from one place to another. It is well known that the glaciers of the Alps, and the Icebergs formed every winter at the mouths of the great rivers in the northern regions of America, envelope immense collections of stones. It is supposed that if a torrent of water broke it up, the ice would float along with its load, and deposit it gradually as it advanced and melted. The extraordinary blocks of granite on the shores of the Baltic may thus, it is supposed, be accounted for, as well as those of the Alps.

We do not intend at present to discuss the hydrostatical accuracy of Sir James Hall's theory. But we may state, that an operation, the very reverse of that which he supposes, would produce a wave without any deviation from the laws of hydrostatics, and account for all the appearances observed during earthquakes. Instead of the land rising, we may suppose it to burst, and lay open extensive hollows, into which the water would rush, filling up the vacuum occasioned by the escape or condensation of the elastic vapours which caused the fracture. Powerful currents would immediately be produced, all tending to a centre; and the velocity acquired would be such, that, after the vacuity was filled, the collision of so many currents at one point, would raise the water to a great height. The retreat of the water from the shore might be explained as well in this way, as by supposing the bottom of the sea to have been raised. The heaving of a mass of land entirely out of the sea, or its sudden submersion, would also produce great agitation in the water; and in every case the operation of subterranean heat in producing elastic vapour, might be retained.

Professor Playfair, the able illustrator of the Huttonian theory, differs widely from all those who are disposed to call in the aid of extraordinary causes and effects, to account for the enormous collection of loose, heterogeneous materials which, for the most part, form the surface of the land. At the time when Mr Playfair wrote, the subject had not been fully stated by any of the partisans of a deluge; and he acknowledges that he has been combating an unseen enemy. Sir James Hall has now stated one side of the question; but he has not by any means exhausted the facts and arguments which tend to corroborate the opinion, that a deluge has swept the face of the earth, and caused that arrangement of the surface which we now observe. We intend to prosecute an examination, already begun, of some districts in which facts illustrative of this subject abound; and we hope in a future article to give a more ample and distinct view of the subject, than it admits of at the present time. The chief object of research ought first to be, to discover whether, in reality, there exist any facts which seem to owe their origin to some extraordinary operation of water; and when such an operation shall be deemed necessary, it will be time enough to make attempts to reconcile it with natural causes and effects.

We close this brief notice with stating a fact which seems to have escaped the observation of diluvian speculators, and which is doubtless of no small importance in the question concerning the animals whose remains are found in northern climates, having belonged to one farther to the south. If we suppose that a torrent has swept the earth, we should expect to find the exuviæ of the human race, as well as those of inferior animals. But this has never occurred, even to the observation of the indefatigable Cuvier; and the alternative is, that the human race did not exist at the time when the supposed catastrophe happened. See Saussure's *Voyages dans les Alpes*, vol. i.; Pallas' *Observations sur la formation des Montagnes*, p. 71, Petersbourg, 1782; *Nov. Comment. Petropol*, tom. xvii. p. 576.; De Luc *Lettres sur l'histoire physique de la terre*, p. 233, &c.; Playfair's *Illustrations of the Huttonian Theory*, p. 412; Cuvier's *Essay on the Theory of the Earth;* and Sir James Hall *On the Revolutions of the Earth's Surface*, in the Edinburgh Transactions, vol. vii. p. 139—211. (S. K.)

DEMERARY, a settlement in Guiana in South America. The river Demerary, from which this settlement derives its name, after a north-easterly course of about 200 miles, falls into the Atlantic Ocean, in latitude 6° 50′ north, longitude 58° west from London. At its entrance, the river is a mile and a half broad, and is navigable for ships of considerable burden, for about 100 miles: well cultivated plantations adorn its banks for nearly another 100 miles inland; when the navigation is obstructed by cataracts, the wild and mountainous scenery of which, though forbidding to industry, attracts frequent parties of pleasure. A little above these cataracts, two streams unite to form the Demerary, the one flowing from the south-east, the other from the south-west, the sources of which, however, have not been explored by Europeans. The Demerary, sheltered from every wind, and never visited by those hurricanes, so frequent in tropical climates, forms one of the finest harbours in the world, and could contain with ease all the navy of Great Britain. Unfortunately, however, a bar of mud stretches across its mouth, over which no vessel drawing more than nine feet can pass until half flood: at high water in spring tides, the bar is covered to the depth of eighteen feet, but still requires very cautious navigation.

The country of Demerary, for many miles from the shore, consists of fine savannahs, in which not a mountain, hill, or even a mole heap occurs, to diversify the landscape. About twenty miles from the mouth of the river on its western bank, there are some hills of sand, from 100 to 150 feet high, and nearly perpendicular. In ascending towards the source, the country becomes more varied and mountainous.

The scenery along the banks of the river, though uniform, is pleasing. Plantations regularly ranged on either side; dwelling-houses built close to the river's brink; buildings of different descriptions, scattered without order in every direction; on the sugar estates, mills driven by wind, by water, or by cattle; on the coffee plantations, *logies* or barns, three stories high; form a very picturesque and beautiful prospect; while boats continually sailing up and down the river, give animation to the scene, and afford a favourable idea of the industry of the inhabitants. The plantations along the river, as well as in the other parts of Demerary and the adjoining colonies, were surveyed, and laid out in allotments of five hundred acres, by the Dutch West India Company; with a conditional grant of as much more behind the first, when two thirds of it should be cultivated: to this grant all the estates on the river are now entitled. Every plantation has a wharf, or landing place, opposite the dwelling-house; and is surrounded by canals, with sluices, for the double purpose of draining from the land all superfluous moisture, and of harbouring boats, while they are loading and discharging. Thus every estate is completely insulated; and for the convenience of travellers, a bridge is thrown over the canals on each side, which the proprietor is obliged to keep in repair, and to have painted white, that they may be discernible in the dark. The only articles of cultivation are sugar, coffee, and plantains, with a small quantity of cocoa and rice. Though the culture of rice was but recently introduced, no doubts were entertained of its success; and it was even hoped that, if encouraged by government, it would rival that of South Carolina, a country which Demerary strongly resembles in climate. The live stock on a Demerary farm consists chiefly of poultry, with a few sheep, oxen, and swine. Rearing stock for the markets, particularly horned cattle, is here very profitable; and the fine savannahs in the interior afford so excellent pasture, that there is every reason to hope that these colonies will, in a short time, rear such numbers of cattle as will prove an abundant source of wealth to the grazier, and an unfailing supply to the West India islands. It is on his sugar, however, that the planter chiefly depends. Of this valuable commodity, the soil of Demerary, when properly cleared and prepared, yields very abundant crops: and the rum distilled from the molasses is calculated to defray all the expences of a sugar estate. Eighty gallons of rum are expected from every hogshead of sugar; and the Demerary rum has a richness of flavour, which gives it as high a preference in the American markets, as Jamaica rum has in England.

Of the value of this colony, some idea may be formed from the following statement of the produce cleared from the port of Demerary, for the three first years after the last establishment of the British custom-house.

From the first of October 1803 to the 10th of September 1804, in 394 vessels,—19,638 hogsheads, 213 tierces, and 161 barrels of sugar; 4887 puncheons of rum; 46,435 bales of cotton; 9,954,610 pounds of coffee; and 311 casks of molasses.——From the 10th of September 1804 to the 5th of January 1805, in 71 vessels,—2161 hogsheads, 78 tierces, and 19 barrels of sugar; 504 puncheons of rum; 6318 bales of cotton; 439,520 pounds of coffee; and 311 casks of melasses. ——From the 5th of January 1805, to the 5th of January 1806, in 200 vessels—15,839 hogsheads, 213 tierces, and 429 barrels of sugar; 3611 puncheons, and 17 hogsheads of rum; 21,202 bales, and five bags of cotton; 2,295,701 pounds of coffee; and 1694 casks of melasses.——From the 5th of January 1806, to the 5th January 1807, in 221 vessels—19,337 hogsheads, 474 tierces, and 801 barrels of sugar; 4722 puncheons, and 17 hogsheads of rum; 23,604 bales, and two bags of cotton; 12,390,102 pounds of coffee; and 1694 casks of melasses.

While cultivation had yet made but little progress, the district of Demerary was deluged by frequent torrents of rain. As the land was cleared, the climate likewise was improved; and two wet and two dry seasons now mark the revolution of the year. Each of these seasons continues for three months. During the rainy seasons, which include the months of December, January, and February, and of June, July, and August, the thermometer is lower than at other times; the land-winds, which are deemed unhealthy, prevail; and the swarms of musquitoes are extremely troublesome. The dry season is extremely fine; the morning twilight commencing at four, gradually unveils a clear azure sky, which continues cloudless throughout the day; at six in the evening the sun sinks at once beneath the horizon, leaving the country in sudden darkness. This length of twilight in the morning, and the total want of it in the evening, may perhaps be occasioned by the sun's rising over the sea, where the atmosphere is very reflective, and setting behind high mountains, whose shadow has definite limits. From seven to ten the heat is almost intolerable; the sea breeze, then arising, restores nature to animation, and continues to blow with increasing vigour till sunset, but subsides about ten at night. During the months in which the West Indies are ravaged by hurricanes, Demerary is affected only by heavy squalls of wind, which do no other injury than blowing down a few acres of plantain trees. Clouds piled on clouds are now seen moving towards the south; hollow peals of thunder are heard in the interior; and the day generally closes with faint flashes of lightning from the south and south-west. The length of the day varies from thirteen to fourteen hours. The range of the thermometer on the sea coast in the dry season, which is the hottest, is from 84° to 90°; at the distance of twenty miles in the interior, the degree of heat seldom exceeds 80° in the warmest part of the day; and at night is generally as low as 50° or 60°.

An account of the diseases incident to this climate, and of its animal and mineral productions, will be given, with more propriety, under the article GUIANA.

The towns in Demerary are Stabroek, the capital; Kingston, an English village, first reared in 1796; Labourgade, consisting of a range of warehouses on the bank of the river; Cumingsburgh, a regularly built town about two miles in circumference; Bridge-town, and New-town; and the village or town of Werk en Rust. The houses in all these towns are generally built of timber on brick foundations, two stories high, and painted white.

Demerary, originally colonized by the Dutch, was wrested from them by the English in 1796; when a number of British adventurers resorted to it. The greatest respect was paid, however, to the existing laws, and to private property; the persons of individuals were held sacred; and even the floating property embarked in colonial vessels was secured to its possessors. This colony was rashly ceded at the peace of Amiens, to the serious injury of many British planters and merchants. It was re-taken in 1803; and it is to be hoped that no trifling consideration will induce ministers in future to relinquish a possession of such importance. (*k*)

DEMOCRACY. See GOVERNMENT.

DEMOCRITUS, a celebrated Grecian philosopher of the Eleatic School, was born at Abdera, a city of Thrace, about five hundred years before the Christian æra. He was one of the earliest propagators of the atomical theory; which was originally invented, it is believed, by his master Leucippus, matured into scientific form by the labours of Epicurus, and transmitted to posterity in the ingenious philosophical poems of Lucretius.

The circumstances of the life of Democritus are inextricably involved in the impenetrable obscurity of ancient fabulous traditions; indeed, if we except Pythagoras, there is none among the Grecian philosophers, to whom so many marvellous acts, so many follies, and so many absurd writings are ascribed. Like most of the early sages of Greece, he is said to have travelled, in quest of knowledge, into the remotest regions of Asia and Africa; and having, at length, by means of his extensive travels and observations, acquired a vast accumulation of general and profound science; he determined to fix his abode at Athens. To this city, therefore, he repaired, and voluntarily surrendering all his property to the state, reserved to himself only a small garden, where he devoted himself to privacy and contemplation. The most hidden *arcana* of nature, it is said, were developed to his penetrating eye, and antiquity boasts of the miracles he performed, by means of the powers with which his knowledge supplied him, as well as of the predictions by which he astonished his contemporaries. His whole life, we are told, was devoted to the investigation of the properties of herbs, minerals, and other productions of nature; and with the view of prosecuting his researches undisturbed, he is reported to have retired into the dwellings of the dead. At the same time, it is somewhat inconsistently related of this indefatigable observer of nature, that he was mad enough to tear out his own eyes; and although withdrawn from the society of his fellow-creatures, that he constantly laughed at the follies of mankind. All these absurd stories were faithfully recorded and implicitly believed by the most eminent Greek and Roman authors; and in the first ages of Christianity, Democritus was generally considered as one of the earliest professors of the art of magic. The eccentricities of this philosopher, we are informed upon no less doubtful authority, induced a belief among the vulgar, that he was disordered in his mind; but Hippocrates, the celebrated physician, being sent to cure him, soon discovered the mistake, and found him to be one of the wisest men of the age.

Democritus was one of the earliest and most successful experimental philosophers; and to his proficiency in science he was probably indebted for his reputation as a magician. So ardently was his mind engaged in the pursuit of knowledge, that he is said to have declared he would prefer the discovery of one cause in the works of nature to the possession of the Persian monarchy. His opinions in regard to the origin and formation of the world, were nearly the same with those which had been previously held by his predecessor, Leucippus. Matter, which he considered as self-existent, he supposed to have been originally divided into an infinite multitude of primary or elementary particles, of which some were eternally intelligent, while others were eternally senseless and incogitative; the latter being incapable of resisting the action of the former, by whose union with them, and controul over them, the visible world was produced. This theory, in the hands of Epicurus, afterwards assumed a more rational and scientific form. See ATOMICAL PHILOSOPHY. In astronomical science, Democritus made some important observations and discoveries. He was the first who taught, that the whiteness of the milky way was occasioned by the confused light of an infinity of stars; an explanation of that phenomenon which was adopted, in later times, by Dr Herschel. And he maintained, though upon erroneous principles, that more planets existed than had been hitherto discovered; a conjecture which has been verified by the observations of astronomers, after an interval of many centuries. In chemistry, Democritus appears to have made successful experiments and researches; several inventions being ascribed to him, which argue no inconsiderable progress in chemical science.

Democritus lived to a very advanced age; and the circumstances attending his death are thus recorded by the ancient writers. Some time prior to his decease, his friends seeing him suddenly reduced to a state of extreme debility, became apprehensive that his end was at hand. His sister, who was at that period engaged in celebrating the festivals of Ceres, declared, that if he then died, she should not be able to perform her vows; upon which the philosopher requested her to supply him with cordials of a particular description, which prolonged his life until her religious rites, which occupied three days, were completed; and when that time had expired, Democritus, exhausted by the pains he endured, hastened, by his own act, the slow approach of death,—

Sponte sua leto caput obvius obtulit ipse;

thus, by his example, giving sanction to a practice, which, although reprobated by the more enlightened doctrines of Christianity, was neither unusual nor accounted criminal among the sages of antiquity. See Meiners, *Geschichte d. Wissensch. in Griechenl, u. Rom.*; Brucker; Bayle; and Mason Good's *Lucretius.* (z)

DEMON. This word is of Greek origin, and is supposed to come from the verb δαιω, the primary meaning of which appears to have been, that of separating into parts, by cutting instruments or other violent means. Hence the verb just mentioned signifies to divide, to distribute, *to reduce by fire*, and following out the idea of separation into parts, to examine in detail, to search, to learn. In conformity with these statements, the word demon will signify a being, who assigns to man his *portion* of enjoyment or of suffering, (παρὰ τὸ δαῆναι τὰ παντα, η μεριζειν τὰ ἀγαθὰ ϗ κακα τοῖς ἄνθρωποις, Proclus in Hesiod,) or it will signify an agent superior to human beings in respect of intelligence, and that species of efficiency which is connected with the possession of knowledge. In some of the Greek writers, the phrase ὁ δαιμων, and the corresponding phrase τὸ δαιμονιον, are used to signify the divinity in general "τὸ θεῖον, *deus supremus, et divinitas mundi moderatrix.*" ὁ δαιμων appears occasionally to be used in this sense by Xenophon, in the *Memorabilia* of Socrates. τιμα τὸ δαιμονιον is a well known precept of the ancient moralists; and Plutarch in *Galb.* says, that thunder and lightning proceed "απο τȣ δαιμονιȣ" from the divinity. The word demon appears next to have signified any one out of the number of the gods. It is applied in this sense to Venus, *Iliad*, iii. and in *Iliad*, xvii. line 98, 99, compared with 104, we find an instance where δάιμων and θεος are used by the poet as equivalent expressions:

Ὁππότ' ἀνηρ ἐθελει προς δαιμονα φωτὶ μάχεσθαι
Ὅν κε θεος τιμᾷ, ταχα οἱ μεγα πημα κυλίσθη·

The word in question seems next to have been applied exclusively to the inferior divinities, or those called the *Dii indigetes, sive minorum gentium.* In this sense θεος is distinguished from δαιμων, and hence the phrase in common use among the Greek writers, θεοὶ ϗ δάιμονες. Of the sense now under consideration, we have a remarkable example in the oration of Æschines against Ctesiphon, 'ὦ γη (says the orator) ϗ θεοι, ϗ δάιμονες ϗ ἀνθρωποι, ὅσοι ϐȣλεσθε ἀκȣειν ταληθη'· In the progress of thought and of language, the idea implied in the term demon appears to have been farther reduced, and the word seems to have been employed to denote a certain class of beings not very well defined in their attributes and character, but considered as holding an intermediate place between gods and men, and corresponding to what in modern times we should denominate *genii*, (simones, quasi semi homines, minores diis, et majores hominibus, *Liv.* viii. 20. Adam's *Rom. Antiq.* p. 287). These of course were either benignant or malign, the δαιμονες κακοι, or πονηροι, and the δαιμονες αγαθοι. The word appears to have this sense in such phrases, as "the demon of the king," the "demon of Socrates," and perhaps too, it was used in this sense, when Parrhasius was said to have painted allegorically the genius (demon) of the Athenians, representing it according to Pliny, as "varius, iracundus, injustus, inconstans," *Nat. Hist.* xxxv. 36. In a still greater reduction of the idea, the word demon is used as equivalent with *fortune*, viewed in the light of a presiding power; hence the phrase καλα δαιμονα, *omine fausto, prospera.* And last of all, we find it employed in the sense of casualty, or chance in life.

In the books of the New Testament, both the words, which are properly rendered demon, namely δαιμων and δαιμονιον, are to be met with; and δαιμονιον in particular is of very frequent occurrence. Neither of them is well translated by the term *devil.* This last word is the proper version of διαϐολος, when applied to the chief of the apostate angels, but not of δαιμων, or δαιμονιον. Indeed our translators themselves appear in some instances to have been sensible of this; for in the account which is given of the effect produced by the preaching of St Paul at Athens, they have rendered the words "'Οι δε ξενων δαιμονιων δοκει καλαγγελεῦς ἔιναι," by "Others said, He seemeth to be a setter forth of *strange gods;*"—Jesus and the resurrection (Ιησȣς ϗ Αναστασις) being taken for new divinities, the one a male and the other a female. The propriety of this version is abundantly evident. Had our translators followed their usual practice, and rendered the words, "He seemeth to be a setter forth of *strange devils,*" they would not only have perverted the meaning of the original text, but would have represented these Athenians to the English reader in a light most truly ridiculous. Ingenious men, or men possessing a certain share of natural acuteness, though unacquainted with the Greek language, might have proposed their solutions; but the common reader must have remained for ever at a loss to conceive, how Jesus and the resurrection, allowing that the Athenians regarded the one of these as a male divinity hitherto unknown to them, and the other as a female, could, with any measure of propriety or of decency, be called *strange devils.* Our translators, therefore, have done wisely in rendering *ξενων δαιμονιων*, by "strange gods." Nor are there wanting other examples in the books of the New Testament, where the Pagan divinities are mentioned under the name of demons. (See 1 Cor. x. 20. and Rev. ix. 20.) In general, however, the demons of holy writ are malignant spirits. We are not informed very particularly about their origin or destiny, but we find them represented as *πνεῦματα ἄκαθαρτα*, and *πνεῦματα πονηρα*, unclean and evil spirits, and according to the received opinion, we must consider them as in league with the devil, (Ὁ *διαβολος*, ὁ *Σατανας*, ὁ *Δρακων* ὁ *μεγας*, &c.) as the subjects of his dominion, and the instruments of his will. They were the immediate agents in all possessions, and to expel or restrain them, or to cure the diseases which they were supposed to occasion, was one of the miraculous gifts of the early times.

The reader who is acquainted with the subject, will perceive that we are now on the borders of the controversy which was agitated about the middle, and towards the end of the last century, by Dr Farmer and his opponents. In the controversy alluded to, of which we shall attempt to give a short account, it was contended, on the one hand, that the demoniacal cases recorded in the books of the New Testament, were instances of real possession; and on the other, that they were merely diseases, set forth under the notion of possessions, in conformity with the belief which was prevalent at the time. By the one party, the language of holy writ was interpreted literally; and by the other it was considered as figurative, and used in the way of accommodation to the existing opinions. We shall not pretend to decide this controversy, but shall rather endeavour, as candidly and impartially as possible, to furnish our readers with the means of deciding it for themselves.

The leading asseveration of Dr Farmer upon the general question, is, that miracles, or works surpassing the power of man, are never performed without a divine interposition; and by a divine interposition he means, either the immediate agency of the Deity himself, or of beings empowered and commissioned by him, And the proof of this asseveration, he tells us, may very easily be found, if we consider, that on any other supposition, it is impossible to shew that a religion supported by miracles is really from God. For the miracles in question, or works surpassing the power of human beings, may have been performed by evil spirits, acting independently of the Divinity, thwarting his purposes, and marring the operation of his goodness. Should it be said, that, from the tendency of the miracle itself, and *a fortiori*, from the tendency of the miracle and religion when taken together, we may easily infer the character of the being from whom the whole scheme proceeds,—to this also Dr Farmer is ready with his answer. "With regard to doctrines," says he, "of a moral or useful tendency, it is not, in all cases, easy for the bulk of mankind, or even for the wise and learned, to form a certain judgment concerning them. What to men appeared to have a tendency to promote virtue and happiness, superior beings, who discerned its remotest effects, might know to be a curse rather than a blessing, and give it countenance from a motive of malevolence. On the other hand, a doctrine really subservient to the cause of piety and virtue, men might judge to be prejudicial to it. And were the sanctity of the doctrine ever so evident, it would not (on the principles of those with whom we are here arguing) certainly follow from hence, that the miracles recommending it were wrought by God; inasmuch as other beings, from motives unknown to us, might interest themselves in favour of such a doctrine." *Essay on Miracles*, p. 87. In one word, according to this author, we do not know whether the tendency of the miracle or of the religion be good or not, and therefore we can form no accurate idea of the character really belonging to the being from whom the revelation proceeds. To our eyes, the system may appear well calculated to promote our happiness, but it may have been the contrivance of wicked spirits. According to the sense and discernment of men, the miracle is useful in itself, but we cannot be sure whether it may not have been performed by one of the rebellious angels "who kept not their first estate." In conformity with these opinions, Dr Farmer maintains, that there is not an instance recorded in sacred scripture, where a miracle has been wrought, and where there is not sufficient reason to believe, that the effect was produced, either by the Deity himself, or by agents commissioned and impowered to act in his name. Hence he considers the Egyptian magicians as jugglers; the witch of Endor as a ventriloquist; and completing the system, he has written an elaborate dissertation to prove, that when Christ was "tempted of the devil," as the Evangelist Matthew expresses it, that apostate angel was not really present, and that the whole transaction took place in a vision or a dream.

With regard to the demoniacs of the New Testament, Dr Farmer observes, that among the Jews, certain diseases, such as madness and epilepsy, were usually ascribed to the agency of evil spirits. This was the current notion and belief of the country. Upon this notion the ordinary phraseology was built. Our Lord and his apostles adapted their instructions to this prevailing notion, and used the language which had been formed upon it, just as Moses, in his account of the creation, adapts himself to the popular astronomy of his time, instead of laying before us the true system of the heavenly bodies. He speaks, not in relation to what is physically correct, but in relation to what was believed. He founds his instructions upon the ideas already entertained by the people to whom the revelation was first communicated: And Christ and his apostles (as Dr Farmer will have it,) do the very same thing. They speak of the demoniacs, not according to the real state of the case, but according to the notions which the Jews entertained of it. Not a few of those demoniacs appear to have been persons of a disordered understanding, subject to attacks of *mania*; some of them were afflicted with the epilepsy, or falling sickness, some were deaf, and others were dumb. When a demon is said to enter into a man, the meaning is, that his madness is about to show itself in a violent paroxysm; when a demon is said to speak, it is only the unhappy victim of the disease himself that speaks; and when a demon or devil is expelled, the exact truth of the case, as well as the whole amount of the miracle, is nothing more, than that the disease is cured. Occasionally, too, say those who contend against the reality of demoniacal possessions, the language of the sacred books confirms the explanation which has just been given. Thus in the 10th chapter of St John's gospel, we find the Jews saying of Christ, "he hath a devil and is mad," as if the expressions were perfectly equivalent. And the person who is represented, in the 17th chapter of Matthew as a lunatic, is spoken of by St Mark as vexed with a dumb spirit. "Besides," says Dr Campbell, (though he held an opinion upon this subject very different from that of Farmer,) "it was a common idiom among the Jews to put *spirit* before any quality ascribed to a person, whether it be good or bad, mental or corporeal. Thus, the spirit of fear, the spirit of meekness, the spirit of slumber, the spirit of jealousy, are used to express habitual fear, &c." *Translat. of the Gospels*, vol. i. p. 251. ed. 1803.

It is farther urged on this side of the question, that the instances of possessions recorded in the books of the New Testament, have all the features and appearance of ordinary diseases. The madness shows itself in these cases, just as it shows itself in the cases which occur among ourselves in the present day: it is now melancholy, and the patient is silent and sullen, and now it vents itself in bursts of anger and ferocious resentment. And the epilepsy of the sacred books is the epilepsy of all our systems of nosology; the phenomena of the diseases are precisely the same. Nor does this detract (in the opinion of Dr Farmer) from the very high character which Christ undoubtedly sustains in the inspired writings, or diminish the value of his miracles as the evidences of our religion; since it must be allowed, that to cure a disease with a word or a touch, is an effort of power, far beyond the reach of any human being. And let it be remembered, that those who deny the expulsion of demons, are ready to admit that diseases were miraculously cured. There is a miracle in either case; and in either case, it is a sufficient proof of our Saviour's mission, and an adequate support of the Christian faith.

To these statements and reasonings, the advocates of possessions have not been slow to reply. Indeed, on every inch of the ground to which the preceding observations refer, they declare themselves willing to join battle with their antagonists. They call in question the truth of Dr Farmer's leading asseveration, namely, "that extraordinary works have never been performed without a divine interposition," and contend, that as human beings have a certain sphere and agency allotted them, so it is reasonable to believe that malignant spirits have a wider sphere and an agency less controulled; and that within this sphere, and in the exercise of this agency, they perform actions, the tendency of which is to thwart the purposes of the divine beneficence, and to introduce confusion and misery into the world. They argue too, that the devil himself, the chief of the apostate spirits, is often represented in holy writ, as exerting his malignity in opposition to the designs of infinite goodness; and in the case of our first parents, as a remarkable example, he tempted them to disobedience, and led them to their fall. It was in consequence of his machinations, that they brought down upon themselves the wrath of heaven, and were driven from the garden in which "the Lord had placed them." The advocates of possessions contend still farther, that the revelation which is made to us in sacred scripture is addressed to our understandings; that it is not only in our power, but that it is our indispensible duty to examine it, and to judge of it; that the tendency of any miracle, or system of doctrine, is a sufficient evidence of the character belonging to him who performs the miracle, or publishes the doctrine; that good actions are demonstrative of the quality of goodness; and, in short, that a religion calculated to make us happy, must have proceeded from a being who has consulted and provided for our happiness. Nor is this a matter so abstruse and remote from human apprehension, that we can form no opinion about it. For, say they, if any thing connected with Christianity be plain, it seems to be, that the tendency of the religion is beneficent, and that it is no less pure in its character than blessed in its effects. The very miracles recorded in scripture are proofs of goodness. They must have been wrought by a good being. And (they continue) we think ourselves entitled to hold our religion as true, and to regard it as in the highest degree beneficial, though we might allow, at the same time, that the magicians of Egypt performed many wonderful works by the agency of wicked spirits, that the sorceress of Endor was in league with the powers of darkness, and that Christ was literally tempted "of the devil," in the wilderness of Judea.

With regard to the more specific question of demoniacal possessions, they are equally bold. They assert, that though God has often been pleased to accommodate himself to our apprehension, by adopting the current language of the countries where the revelation was first published; yet the account of the creation given by Moses is not altogether an instance in point. For (say they) while it is granted that the true system of the universe is not laid before us in the first chapter of Genesis, it ought to be remembered that the statements in that chapter are exceedingly general; and that, while the whole truth is not told, it being no part of the revelation to tell it, there is, at the same time, no error directly inculcated. In the demoniacal cases, however, the conduct of the inspired writers, and indeed of Christ himself, is widely different. They positively and directly inform us, that a demon "enters into" a man, and "comes out" of him; they represent the demons as speaking and reasoning, and hoping and fearing; as having inclinations and aversions peculiar to themselves, and distinct from those of the person who is the subject of the possession; they tell us of one unhappy sufferer who was vexed with many devils; and, in the case of the demoniac of Gadara, they assure us, that the devils were "cast out" of the man, and were permitted, at their own request, to "enter into" a herd of swine which were feeding in the neighbourhood, and that immediately the herd ran violently down a steep place, and were drowned in the sea. Who ever heard of swine afflicted with madness as a natural disease? Or when and where has the epilepsy, or falling sickness, been predicable of the sow? For (say the patrons of possessions) it must be carefully observed that the disease of the man, the affection of the human sufferer, whatever that affection might have been, was clearly transferred from him to the animals in question. Besides, as various instances are recorded in scripture, and as several of these instances are given at considerable length, might we not expect, if possessions were really nothing more than ordinary diseases, that the truth would be somewhere told or hinted at? that, within the compass of the sacred canon, something would be said, or something insinuated, which would lead us to understand, that the language, though inaccurate and improper, was used in accommodation to the popular belief? Might we not expect that Christ himself would have declared, in one unequivocal affirmation, or in some intelligible way, the exact truth of the case? Or, at all events, when the Holy Ghost had descended upon the apostles on the day of Pentecost, and when the full disclosure of the revelation appears to have been made, might it not reasonably have been looked for that the popular error would have been rectified, and the language reduced from its figurative character to a state of simple correctness? What conceivable motive could influence our Saviour, or his apostles, to sanction the delusion of the multitude? And does it not strike at the root of the Christian religion itself, to have it thought, for a single moment, that its "author and finisher," who came to enlighten and to reform the world, should have, on so many occasions, not only countenanced, but confirmed, an opinion which he must have known to be "the reverse of the truth."

Let us beware, (say the antagonists of Farmer,) how we relinquish the plain and literal sense of holy writ, in search of allegorical or figurative interpretations. And if, upon any occasion, we think it proper to do so, let us consider well the grounds and reasons upon which our determination is built. It is evident (they affirm) that the devil and his angels, according to all that we can learn of them in the sacred books, are real beings, that the demons of the New Testament are malignant spirits, and that they act upon the same principles, and even under the authority of Satan himself, who is otherwise called Beelzebub, and the Prince of the Devils. Nay, in these very cases of possession, the chief of the apostate angels is clearly set forth as acting either in his own person or by means of his infernal agents. And it is on this supposition alone that we can explain the language of Christ in that remarkable declaration which he makes to the Pharisees and rulers of the Jews, and which we find recorded in the 12th chapter of the gospel by Matthew. "The Pharisees heard it," observes the evangelist, "and they said, This *fellow* doth not cast out devils but by Beelzebub, the prince of the devils. And Jesus knew their thoughts, and said unto them, every kingdom divided against itself is brought to desolation, and every city or house divided against itself, shall not stand: And if Satan cast out Satan, he is divided against himself, how shall then his kingdom stand?"

A principal argument with those who contend for the reality of demoniacal possessions is, that the inspired writers uniformly make a distinction between diseases occurring in the ordinary course of nature, and diseases occasioned by the agency of evil spirits. This argument seems to be regarded as conclusive by Dr Porteous, Bishop of London, in his Lectures on the gospel of St Matthew. He represents the distinction alluded to as plain and frequent. "There is every where," says he, "a plain distinction made, between common diseases and demoniacal possessions; which shows that they are totally different things. In the 4th chapter of this gospel, (St Matthew,) where the very first mention is made of these possessions, it is said that our Lord's fame went throughout all Syria, and that they brought unto him *all sick people*, that were taken with divers diseases and torments, and those *which were possessed with devils*, and he healed them. Here those that were taken with divers diseases and torments, and those possessed with devils, are mentioned as distinct and separate persons: a plain proof that the demoniacal possessions were not natural diseases; and the very same distinction is made in several other passages of holy writ. There can be no doubt, therefore, that the demoniacs were persons really possessed with evil spirits; and although it may seem strange to us, yet we find from Josephus and other historians, that it was in those times, no uncommon case." See *Lectures on St Matthew*, vol. i. p. 264.

Such is a concise view of the argument on both sides of this abstruse and difficult question. We are not aware that we have misrepresented, in any material circumstance, the sentiments of either party. But the subject of this article is by no means exhausted by what we have said. It remains for us to treat of the demonology of the middle ages, and the influence, real or supposed, of wicked spirits, in more modern times. But for some curious information on those topics, we refer to another part of our work. See WITCHCRAFT. On the subject of the present article, our readers may consult the following works of Dr Farmer: *Essay on Miracles; Essay on the Worship of Human Spirits; Essay on the Demoniacs of the New Testament;* and the *Essay on our Saviour's Temptation in the Wilderness.* Also Campbell *On the Gospels, Prelim. DEMONIACK. See DEMON.

DEMOSTHENES, the Athenian orator, was born in the 4th year of the 99th Olympiad, and 381 years before Christ. His father was an Athenian born, but his maternal descent was partly Scythian. The Athenians had proceeded from trading with the natives, to form a settlement on the shores of the Tauric Chersonese, now called the Crimea. Gylon, an Athenian, was, under the appointment of his own republic, governor of this settlement or fortified factory, when the sovereign of the country desired to regain possession of it. Despairing, however, of being able to carry it against the skilful fortifications of the Greeks, he entered into a negociation with the governor, who, for the bribe of a town and territory, and the promise of a rich Scythian heiress in marriage, surrendered Nympheum to the barbarous potentate. Of course he could no longer appear at Athens, but possibly hoping to form some connections in his native city, so as to open a way for his pardon, he sent his two daughters to Athens. One of them married a man of eminence, Demochares; the other took for her husband Demosthenes, a citizen of the Pacanian ward, by trade a sword-cutler, and the father of the chief of orators. Demosthenes was left an orphan at seven years of age, with a very delicate constitution, but with a fortune, which, though it might have been partially dilapidated by his guardians, was still sufficient to rank him among the wealthy. According to the general account, his education was neglected. Mr Mitford, in his recently published and valuable history of Greece, has made it certain, from the orator's own authority, that he was not, as Plutarch represents him, illiterate at the commencement of his professional studies. Educated, says that author, (Mr Mitford) as became his fortune, and introduced into life advantageously through his connection with Demochares, he was of course to take his share of the combined toils and honours, which the Athenian constitution made the lot of the wealthy. In earliest manhood, he was appointed to the expensive but honourable offices of Choregus, or president of theatrical entertainments, and trierarc or director of the equipment of a ship of war. To the burden of this office was annexed the honour of the command of the ship equipped. But while none of the wealthy were legally excusable from the one, many would be very unfit for the other, which, therefore, was not so rigorously imposed. Demosthenes, though apparently little of a seaman, acted however at one time as a naval captain in the Athenian service. He contributed also to the treasury, as we find him boasting, by a gift called free, but no more to be avoided than the office of trierarc. Through his disposition to luxury and ostentation, (continues the same historian), his fortune was quickly dissipated. On emerging from his minority, (by the Athenian law at five-and-twenty,) he earned an opprobrious nick-name by a prosecution of his guardians, which was considered as a dishonourable attempt to extort money. In fixing this last stain upon Demosthenes' character, with regard to his prosecution of his guardians, Mr Mitford seems to give way rather to his systematic hatred of the republican orator, than to the force of historical evidence. The charge of youthful effeminacy in dress and manner, and even of prodigality, brought against him by his rival Æschines, might or might not be true; but in order to substantiate the accusation of baseness in his plea with his guardians, some better proof is required than the invective of a rival. The fact of his prosecuting those guardians is admitted; and the commonly received account is, that he cast them in damages. Had the decisions of the court of justice been against him, we should have been informed of it by the same hostile channel through which the suspicion of his motives has been conveyed. In the same uncandid spirit, we consider the general moral portraiture of this illustrious man to have been drawn by Mr Mitford. That his life was not unblemished, is but too evident; but to admit the abuse of Æschines as decisive in every instance against it, is the excess of historical acrimony; the more to be regretted that it comes from the pen of a writer so powerful, acute, and learned, as the latest historian of Greece must be confessed to be.

At the age of twenty-five, Demosthenes commenced that employment which had raised Isocrates before him to wealth, consequence, and fame, that of composing speeches for suitors in the court of justice; and from private causes, soon embarked his talents in those of the public. His natural deficiencies for public oratory, and the pains which he took to correct them, are related in almost every sketch of his biography. Some of them are akin to the marvellous, and savour much of the gossipping credulity of Plutarch; in particular, the anecdote of his mode of curing defective articulation, by speaking with pebbles in his mouth as he walked up a hill. Yet the tradition of antiquity, that he conquered impediments and acquired excellence by unbounded assiduity, may well deserve belief.

As Demosthenes was one of the great men who chain the history of their country to their biography, it may be necessary to say something of the circumstances of Athens at the time when he appeared as a public character. From the date of the glorious victories over the Persians, the Athenians, who assumed to themselves the chief honours of those victories, set up as the sovereign umpires of Greece. Their rivalship with Sparta occasioned the Peloponnesian war; after which, the Spartans, for thirty years, established a sovereignty over the petty states, that was much more intolerable than that of Attica. By the aid of Persia, however, Athens was enabled to form a new confederacy for the nominal independence of the Greek states, or, in other words, to transfer their dependence to themselves. They rebuilt their walls, and once more dictated terms to Sparta. Peace had not been long established, when Thebes, under the genius of Pelopidas and Epaminondas, rose to primary importance in the scale of Greece: in her short struggle against both Lacedemon and Athens, she gave a mortal wound to the supremacy of the former power, though she left the power of Athens comparatively unimpaired. Soon after, Olynthus, a city extending its influence widely over the Chalcidic continent, rose also to a formidable degree of consequence, and for a certain time gave a check to the Athenian arms. But the consequence of either Thebes or Olynthus was transitory, compared with that which was now developing itself in Macedon under Philip. Macedon, remote and rude, had hitherto been scarcely numbered among the Grecian nations; but its new sovereign Philip, who had been educated in the Theban school of arms, submitted its barbarous energies to a system of military and political tactics which proved irresistible. Philip, on his accession to the throne, found himself at war with Athens, which supported another competitor to the Macedonian throne. Having defeated the Athenians, he instantly liberated all the prisoners of that nation, and, by a politic act of generosity, sent them home, not only without ransom, but loaded with favours. Peace and alliance were concluded between the republic and Macedon, whose sovereign waved his pretensions to Amphipolis, a city bordering on Macedon, knowing it to be a favourite object of Athenian ambition. By the peace with Philip, Athens revived in political eminence; but the defects in her democratical constitution were coming to a fatal crisis, in the unsteadiness of government, the decay of patriotism and principle, and of military virtue, and in the subserviency of administration to popular passion. Victory, however, for a time attended the Athenian arms, which were turned, for a while, in conjunction with those of Philip, against the state of Olynthus. The alliance of the Athenians and Philip was broken off by events which are still involved in some obscurity, notwithstanding the generally luminous researches of Mr Mitford. According to that author, the whole blame rested on the Athenians, who turned short upon their ally, and with successful treachery instigated the inhabitants of Pydna, (a sea-port town subject to Macedon,) to revolt from Macedon. After which, the Athenians, having refused satisfaction to Philip, seized upon Amphipolis, and with some difficulty succeeded. Two points in this statement are, however, uncertain; the first is, the successful treachery of the Athenians in detaching Pydna from Macedon, which is but very obscurely intimated by the ancients; and, secondly, the fact of the Athenians having seized Amphipolis, of which there is no proof, although it is certain that they attacked it. In about a year from this time, Amphipolis was attacked by Philip, and the Olynthians now at peace and in alliance, were quickly taken. Diodorus's account, however, so far justifies Philip, as it informs us, that this prince had received strong provocation from the city of Amphipolis; and the Athenians, who had no more real title to Amphipolis than the Macedonians, could with an ill grace blame another power for taking possession of what they had themselves attempted to seize. Athens, however, whether her quarrel with Philip was just or unjust, was unable, for the present, to follow the dictates of her resentment. Her maritime oppressions had driven the states of Rhodes, Chios, Cos, and Byzantium, to join in a confederacy for independence, and to declare that they would protect their commerce with their own fleets, and pay no more tribute to that of Athens. This revolt, or, as it was called, the Social War, lasted for three years, and was succeeded by the Phocian, or Sacred War; so called, as it began from a motive or pretence of religion. The Phocians had ploughed up some ground adjoining to the temple of Apollo, at Delphos, which their neighbours and the Amphyctionic council denounced as an act of sacrilege. The Phocians resisting their decree, took up arms to assert their claim to the land. Athens and Sparta declared on their side. The Thebans were their principal opposers.—These were some of the principal public events connected with the field of politics on which Demosthenes was to act so conspicuous a part. It would be digressing too far into the history of Athens, to enter into other circumstances of nearly coeval date, which are connected with the subjects of his orations; such as the politics of Eubœa and Thrace, in which the contending ambition of Philip and the rival republic were vigorously engaged. Two parties now divided the Athenian councils; one perpetually recommending peace and friendship with Macedon, the other breathing only war and views of aggrandisement. The former might consist partly of the secret adherents of Philip, but it also contained a few patriotic men, far above suspicion, of whom were Isocrates and Phocion. At the head of the high democratical war-party was Chares, who bore the most extensive influence over the sovereign and tyrannous many.

Demosthenes was but yet a candidate for that party-connection which might lead to power, when, in the second year of the Phocian war, Chares and his partizans, after peace had been made with the revolted allies of Athens, wanting a field for military adventure, absurdly thought of leading the republic into a war with Persia. Then at the age of nine-and-twenty he delivered the first of his speeches, that seems to have attracted public attention enough to induce its publication; and he spoke in opposition. The orators of the war-party, who had spoken before him, had been endeavouring, by strained panegyric of the heroic deeds of their forefathers against the Persians, to excite the many to concur in their purposes. Demosthenes, in an opening of singular art, elegance, and conciseness, admitting the deeds of their forefathers to have been above all praise, turned their panegyric and argument successfully into ridicule. The Persian court really had no designs, at that time, of proceeding to actual war with Greece. The union of the Greeks was a chimerical idea, as he justly represents, and their partial attack could only expose their weakness. At the same time, he exhorted to preparation against the eventual hostilities of either Persia or of any other foe. In conclusion, he says, "Do not, then, discover to the world the melancholy state of Greece, by inviting those to an alliance whom you cannot gain, and engaging in a war which you cannot support: *Be quiet; be resolute; be prepared.* Let not the emissaries of Persia report to their king, that Greece and Athens are distracted in their councils, are confounded by their fears, are torn by dissensions. No! let them rather tell him, that if it were not equally shameful for the Greeks to violate their honour and their oaths, as it is to him matter of triumph, they would have long since marched against him; and that, if you do not march, you are restrained solely by a regard to your own dignity: That it is your prayer to all the gods, that he may be seized with the infatuation which once possessed his ancestors, and then he would find no defect of vigour in your measures. * * * * * You should prepare your force against your present enemies; you should use this force against the king, (so the king of Persia was always designated,) against any power that may attempt to injure you. But never be the first to break through the bounds of justice, either in council or in action; you should be solicitous, not that our speeches, but our conduct, should be worthy of our illustrious descent. Act thus, and you will serve not yourselves only, but the men who oppose these measures; for they will not feel your resentment hereafter, if they be not suffered to mislead you now." This speech was applauded; and although he was the first, and almost the only one, to oppose the Persian war, his advice was followed.—His next oration was on the subject of the regulation of the state: The war-party having engaged in projects of complex hostility, began to feel their finances fail, and ventured upon the bold attempt of persuading the people to surrender, for the purposes of war, some of those gratifications, which, under the sanction of severe laws, consumed almost the whole of the public revenue. Demosthenes spoke again in opposition, and appeared as the public antagonist of Chares. He resisted the proposed abolition of the distributions from the treasury, and argued, that if war was to be made, the citizens themselves should serve, as in good times of old. The money which the war-party thus proposed to raise, he observed, (probably with great truth,) was to raise a mercenary force for their generals to command, more for their private interest than for any public good. In this oration, his severe allusions to the oppressions which his countrymen exercised over their allies, leave a prepossession in the mind in favour of the spirit which dictated the part which he took.—His next oration was for the Megalopolitans. In order to understand the subject of this oration, it is necessary to turn back to the period when the genius of Epaminondas had put an end to the tyranny of Sparta. The Arcadians and Argives having risen at that period against Lacedemon, the Lacedemonians solicited aid from Athens, who, forgetting her rivalship with Sparta, and fearing Thebes, sent armies to the assistance of the former. It is not to the present purpose to mention the several events in the course of this war; it is only necessary to observe, that the Arcadians, in order the better to secure that liberty for which they contended, determined to collect all their force into one body, brought the detached settlements of their countrymen to an union, and fixed their common residence in a city called Megalopolis, or the great city. The question at Athens was, Whether this rallying point for a people once subdued by the Spartans, should be sanctioned, or not, by their permission? On the one hand was pleaded the common cause of Sparta and Athens; an union of interest which seemed to forbid that any check should be put upon Lacedemon, and the settlement of Megalopolis was considered as likely to be such a check. On the other hand, Demosthenes (it must be owned, without pleading upon the broad principles of justice,) argues for the Megalopolitans, as likely to be allies of more consequence to Athens than Sparta itself; and even contends, that their establishment was necessary to balance the power of Thebes and Sparta. In conclusion, he conjures his countrymen not to abandon the people of Megalopolis, nor any weaker state, to the power of the stronger. The result of the contest is not reported;

but it remains among ancient writers to be gathered, that though the Athenian people were not prevailed upon directly and openly to oppose their allies the Lacedemonians, yet the associates of Isocrates could procure no concurrence in the arrangement proposed by Lacedemon. Demosthenes was now embarked in the highly democratical side of Chares.

The event of the social war has been already noticed. For three years the states of Chios, Cos, and Rhodes, had confederated in resisting the dominion of Athens; and in their fears of the Persian arms, the Athenians had been forced to give a peace, by which it was stipulated that the confederates should be free and independent, or at least that they should pay no other tribute to Athens than such as their respestive representatives residing at Athens should consent to. Rhodes, after this peace, became a prey to infuriate factions. The aristocracy unable to withstand the democratical party, applied to Artemisia, princess of Caria, who held a kind of feudal principality under the Persian empire, and received a Carian garrison into their citadel. The Rhodian democracy applied for aid to the Athenians; and in the assembly convened on this occasion, Demosthenes pleaded their cause. Their cause laboured under difficulties. In the late resistance of Rhodes, the many had been distinguished for their zeal, or for what the imperial republic of Athens chose to denominate, their insolence and ingratitude towards the Athenians. It was well known besides, that the Persian king interested himself on the side of the Carian aristocrats. The clients of Demosthenes, the Rhodian democracy, were the recent and most formidable champions of an independence fought for, and won in despite of Athens; and in speaking of Persia, the orator was obliged to modify or obliterate, as well as he could, the impressions of his former arguments in favour of pacific policy towards the great king. Fearing directly to meet the prejudices of his audience against the Rhodians, Demosthenes took the broad and popular ground of arguing, that it was not the cause of the Rhodes that he was pleading, but the common cause of democracy. Such was the universal connection of the democratical cause; so readily, if variance arose between democratical governments, they fell into concord again, that it would be better for Athens, (he contended,) to be at war with all the states of Greece together, if all were under democratical government, than to have peace and alliance with all under oligarchy. What decree followed we are not informed, but no measures, or none that were effectual, were taken to support the Rhodian petitioners, perhaps because the attention of the Athenian government was forcibly called another way. While the states of Greece were weakening themselves in the sacred war, Philip was extending his frontier without interruption, by taking in such places as were either convenient or troublesome to him. It was not long before he had an opportunity of engaging as a party in the Phocian war. The nobility of Thessaly were scarcely delivered from the yoke of Alexander of Pheræ, when another intolerable tyranny succeeded under Tysophanus, Lycophron, and Pertholaus. These, with the Aleuadæ, the descendants of Hercules at their head, petitioned for Philip's assistance against their oppressors. He marched into Thessaly, and soon divested the tyrants of all authority. After this, he marched against the Phocians, who had supported the cause of the tyrant, and having obtained the most decisive success, advanced as far as the pass of Thermopylæ, with the combined Macedonian and Thessalian forces. His approach naturally alarmed the Athenians, and they met him with a force, before which he thought proper to retire. Previous to this, negociations for peace had been attempted, between Macedonia and Olynthus as confederates on one side, and the Athenians on the other; but they ended in nothing. Within a few years, Philip's conquest of Thrace, his acquisition of the gold mines in that region, his successful interference in Thessaly, the whole progress of his affairs, and the spreading popularity of his name throughout Greece, made him an object of terrific importance to the only Grecian states which retained the semblance of a power to oppose him. At this distance of time, the best informed can only conjecture what would have been the fate of Athens if she had given a fair trial to the repeated declarations of Philip, that he wished not for destruction, and was unwilling to come to extremities with her. The ruling party of Athens, were not disposed to hazard any thing like such an experiment. A triumph which Phocion obtained with the Athenian arms in Eubœa, seemed to promise the entire revival of the milder and more moderate party; but they seem to have never gained it completely. About the end of the second, or the beginning of the third year of the 107th Olympiad, commenced those famous speeches against Philip, from the celebrity of which, their name was adopted by Rome, and afterwards by modern Europe, to designate orations abounding with hostility. The first of these seems not, however, to have produced a decided effect on the actions of the Athenians. They retained their ambition, but not their primitive energy; and Philip, independent of most all men, who dreaded the extreme violence of the war-party, had also his venal partizans, who were favourably heard. The defection of Olynthus, however, from the side of Philip to that of Athens, gave a new turn to affairs. The Olynthians pressed the Athenians for immediate succours. Their ambassador opened their commission in an assembly of the people. As the importance of the occasion increased the number of the speakers, the elder orators had debated the affair before Demosthenes arose. In his first Olynthic oration, therefore, he speaks as to a people already informed, urges the necessity of joining with the Olynthians, inveighs against the designs and ambition of Philip, and labours to remove their dreadful apprehensions of his power, and to put an end to all domestic dissensions. In consequence of the first Olynthic oration, the assembly decreed that relief should be sent to the Olynthians, and thirty galleys, and two thousand men, were accordingly dispatched under the command of Chares. But these succours, consisting entirely of mercenaries, and commanded by a general of no great reputation, could not be of decisive service, and were besides suspected, and scarcely less dreaded by the Olynthians than the Macedonians themselves. In the mean time, the progress of Philip's arms could meet with little opposition, and having twice defeated the Olynthians, he shut them up in their city. In this emergency, they applied for fresh succours from Athens; and the object of our orator's second Olynthic oration, was to prove, that both the honour and interest of Athens demanded compliance. Inefficient succours having been sent, a third Olynthic oration was devoted to the same object as before. Olynthus fell into the hands of Philip, and the Athenians, (Demosthenes himself advising the measure,) thought it necessary to come to negociations for peace. Two several embassies were dispatched from Athens to Macedon, and Demosthenes accompanied both. If we may trust the account of the bitterest enemy, he behaved with ridiculous affectation at the court of Philip. In an unusual situation, to which his temper and habits were adverse, his extensive genius failed him, and the aukwardness of his apologies to Philip, and the absurdity of some of his compliments, are said to have moved the laughter of the by-standers. All this, however, is told on the authority of his oratorial rival.

Peace was established. The Athenian ambassadors, who concluded the treaty, gave, on their return, a favourable account of the appearance of candour and sincerity in Philip; but a violent sensation was produced in the popular mind, by the intelligence that the Phocians, by the influence of Philip, had been deprived of their seat in the Amphyctionic council, and that the double voice which they had enjoyed in it, should be transferred to the King of Macedon. The Athenians had not been present at Philip's election into this council; he thought proper, however, to send them an invitation to come and ratify his election. The proposal raised a violent ferment in the assembly. On this occasion, Demosthenes delivered his oration on the peace. His object is expressly declared by himself to be, to inculcate, that whether subsidies, or alliances, or whatever schemes were concerting for the public good, one point should be secured, the continuance of the present peace. These are his words; but his covert object is evidently, rather to dissuade them from making the election of Philip into the Amphyctions (an object which he calls a mere shadow) the ground of war, than to dissuade them from war altogether. He urges the impolicy of affording Philip such a pretence for war, as would rally round his standard a number of states, who, if the war were declared for a different and more rational object, would either be neutral, or attach themselves to Athens. Two years after this oration on the peace, Demosthenes delivered his seventh against Philip, or as it is commonly called, his second Philippic. The peace of Athens and Macedon had been quickly followed by the most violent political agitations in Peloponnesus. The Thebans, retaining their ancient enmity to Lacedemon, supported the pretensions of Messene and Argos to shake off the Lacedemonian yoke; and certainly with a colour of justice, since the former power had no right over the latter, but the right of the strongest. The Thebans also besought the king of Macedon to assist them in reducing the power of Lacedemon; and he listened to their overture. In this convulsed state of the Peloponnesus, a congress of delegates was held from all, or many of the governments; and Demosthenes had attended this congress, with a view to persuade the Messenians and Argians to throw themselves into Athenian, instead of Macedonian patronage. His eloquence was applauded, but his arguments seem to have failed of effect. The same subject gave again occasion to what is called his second, or otherwise his seventh Philippic, pronounced before the Athenian people. The Lacedemonians had applied to Athens for succour. On the other hand, Thebes, Argos, and Messene, sent representatives to plead for themselves, and to reproach Athens for favouring Lacedemon, the tyrant of the Peloponnesus. Demosthenes, in advising what answer should be given to the Lacedemonian ambassadors, pronounced the whole business to betray the designs of Philip against the best liberties of Greece; and concluded by an accusation of Æschines for having advised, in the recent ratification of peace, the surrender of Phocis and Thermopylæ. The vehemence of Demosthenes determined the Athenians to oppose the attempts of Philip in the Peloponnesus, and his influence with the Argians and Messenians, at length detached those states from the Macedonian alliance. The subject of discord was soon changed from Peloponnesus to the Thracian Chersonese. In the course of the late war, the states of this peninsula had shaken off their dependence on Athens, and bowed to the stronger influence of Macedon.

But while Philip was called off during his truce with Athens, to more remote conquests among the snowy deserts of Eastern Thrace, it seemed a favourable occasion for the war-party of Athens to fix a settlement on the Thracian Chersonese, by which their maritime exactions and influence might again be restored. The conduct of the settlement was entrusted to Diopeithes, a violent character, who seems to have conducted himself entirely in the style of an ancient Buccaneer, burning, destroying, and exacting tribute among those whom Philip had a right to regard as either his allies or dependencies. Philip remonstrated to the Athenians, and many voices were raised for Diopeithes. His cause was taken up by Demosthenes, in his oration on the state of the Chersonese. Here the orator, in his boldest tone, justifies the conduct of Diopeithes, on the tyrant plea of necessity. The republic, he said, had no choice left; it was already at war with Philip, and had no alternative, but to repel force by force. Philip, he maintained, had broken articles of treaties upon record, and seized upon many of their possessions,—a seizure, for the proof of which, he appeals to their own decrees: Philip had, ever since the peace, been arming himself with all the powers of Greeks and Barbarians to destroy them, before the departure of Diopeithes and his colony. The oration had its effect, for, instead of punishing Diopeithes, the Athenians supplied him with money, in order to put him in a condition to continue his expeditions. So far, the war-party was successful; but the entire lead of administration was not yet in their hands, nor was war declared with Macedon, when Demosthenes pronounced his third Philippic, preparatory to an interference of the Athenians in the island of Eubœa; an interference, to which they were invited by Callias, the Chalcidian founder of the Eubœan general assembly. A change in Athenian politics took place at this period, in which we find Demosthenes and Phocion acting in unison, and the office of first minister of Athens filled by Demosthenes. The coalition with Phocion is explained, by the moderate and just manner in which Athens for the first time condescended to act towards a dependent state. Demosthenes not only gave his support to the liberal system adopted towards Eubœa, but, under his management, a treaty was concluded with the states of that island, granting entire independence; and a body of Athenian troops, conducted by Phocion, with little or no effort subdued all the resistance that was made to settling the peace of the island by the Theban or Macedonian troops.* For restoring liberty to the Eubœan cities, and for his various services to the republic, the thanks of the people were voted to Demosthenes, in a general assembly; and a crown of gold was decreed to be presented to him in the theatre, at the festival of Bacchus. With no less wisdom than he had shewn, on a former occasion, in resisting the plan of a needless war with Persia, the orator-minister now

* Mr Mitford doubts that there were any Macedonian troops in Eubœa, but at the same time gives historical authority for the fact of which he doubts.

cultivated connection with that power. An embassy to the Persian court, on his motion, was decreed, and, under his able direction, was successful. A considerable subsidy of money was obtained from Persia. Speculations in Thrace next engaged his attention. An inestimable object for Athens, was to gain the important town of Byzantium, (the site of modern Constantinople,) commanding the commerce of the Euxine Sea. Philip was at this time implicated in a war with Scythia; and the new connection with Persia, could not but give Athens importance in the eyes of the Byzantines, among whom the adverse parties in the interests of Macedon and Athens were still doubtfully balanced. The object of gaining Byzantium appeared so important to Demosthenes, as to induce him to leave the Athenian people, for a time, to the impression of the eloquence of others, while he undertook himself an embassy to Thrace. In proposing his new system of liberal alliance, he seems to have had the concurrence of the party of Phocion. His success evidently was great. In Perynthus, Selymbria, and Byzantium, a preponderance was given to the Athenian party, and between alliance with Athens, and war with Macedonia, the transition was short. Philip returning from his Scythian campaign, immediately began the reduction of the Thracian cities which had abjured his authority, and among these to Perynthus. The fall of this place was delayed by the interposition of Persia, who, alarmed at the progress of Philip's arms, sent directions to the governors of the maritime places, to supply the besieged city with every kind of assistance; while the Byzantines sent into the city the flower of their youth, with all the necessaries for an obstinate defence. The Perynthians then reinforced, were, however, still dependent on the succours of Athens, in whose cause and alliance they considered themselves as suffering. On this occasion, Demosthenes delivered his fourth Philippic, which, in point of argument, is a concentrated repetition of all that could be urged for a war with Philip, but which is animated with an increased confidence in the power of his party, and in the revival of his own favour with a majority of the people.

It is impossible to deny Demosthenes the praise of vigour and activity, in bringing affairs to this crisis; but his connexion with the high democratical party, while it served his purpose of guiding the popular will to decisive hostilities, unhappily involved him in a fatal error with regard to military events. The expedition to relieve the Thracian cities, was consigned to Chares, who, without reputation to insure the confidence of his allies, or conduct to deserve it, wandered along the coasts, extorting contributions, and feared by all his enemies, till he was defeated by the admiral of Philip, and lost the greater part of his fleet. In the mean time, before war was formally declared on either side, Philip addressed a remonstrance to the Athenians, in the shape of a letter, which is still preserved, and is one of the most valuable state papers of antiquity, singularly combining dignity with simplicity, perspicuity with conciseness, civility and moderation of expression with force of argument. On the subject of this letter, Demosthenes delivered another oration, in which he avoids, with singular art, to enter on the facts of Philip's exposition,—affects to consider the letter as an open declaration of war,—inflames the imaginations of his hearers with this idea, and speaks only of the means to support their arms against so powerful an enemy.

When Philip had assembled an army for the invasion of Attica, Demosthenes put himself at the head of an embassy to persuade the Bœotians to take part against him, and by the force of his eloquence, he succeeded, notwithstanding the efforts of Python, an orator of great fame, who was Philip's advocate on the occasion. His triumph, however, met with a severe check, from Philip's subsequent victory over the combined forces at Cheronea, where the orator betrayed a great want of personal courage. It may be but fair charity to the memory of Demosthenes to recollect a similar instance of cowardice in a hero, who afterwards filled the world with his military fame. The great Frederick of Prussia is known to have fled in the first engagement which he ever fought. His opponents at Athens brought Demosthenes to trial for this behaviour; but the people acquitted him, and he was appointed to pronounce the funeral harangue of those who fell at Cheronea.

The death of Philip opened to Athens a false hope of returning power and security; and Demosthenes appeared on the occasion with a garland on his head, though he had but a few days before lost his daughter. A new league was formed, chiefly by his influence, among the states of Greece; but the terrible chastisement which Alexander inflicted on Thebes, broke the courage of the confederacy; and the Athenians found it necessary to send an embassy to the conqueror, in which Demosthenes at first proposed to take a share, but his apprehensions caused him to turn back upon the road. Alexander required him to be delivered up among the other orators; but Demades pacified the king without this sacrifice. Demosthenes having displayed his patriotism by rebuilding the walls of Athens at his own expence, was recompensed by a crown of gold, which was decreed to him. On the decline of his influence, Æschines brought an accusation against him on this subject, which occasioned a solemn trial, and the delivering of his celebrated oration on the crown. Some time after this triumph, occurred the most discreditable anecdote, if it can be believed, which the life of this great man presents. Harpalus, a discarded favourite of Alexander, had fled with his treasures to Athens, where he bribed the orators, and laboured to gain the protection of the state. Demosthenes, at first, urged his countrymen to avoid the danger of entertaining such a guest, and instigated an inquiry into Harpalus's treasures. In looking over them, however, the sight of a golden cup of exquisite workmanship, is said to have struck his cupidity, which he privately accepted from Harpalus, and appeared next day in the assembly with his throat wrapt in wool, as if he had a quinsy, to excuse himself from speaking. Some jests were passed, but more serious consequences ensued; for, on Demosthenes insisting on the matter being brought to a trial, he was found guilty by the Areopagus, and sentenced to a fine of fifty talents. It should be mentioned in behalf of Demosthenes, that Pausanias vindicates his innocence, and mentions, as a proof of it, that an authentic account was sent to Athens after the death of Harpalus, of all the sums distributed by him in this city, and of the persons to whom each sum was paid, and that no mention was at all made of Demosthenes; though Philoxenus, who procured the account, as well as Alexander who received it, were both the personal enemies of Demosthenes. Amidst the corruption and degeneracy of Athens, the sentence of the Areopagus itself ceases to be a decisive proof of guilt, since Dinarchus, the accuser of Demosthenes on this occasion, speaks expressly of a case in which one of its judges had been corrupted. Unable to pay this fine, he was imprisoned, but escaped from confinement, and passed some time in a melancholy exile on the island of Ægina. On the death of Alexander, when a new confederacy was planned by the Grecian states, Demosthenes ventured to leave the island, and, attending the Athenian deputies from city to city, made such efforts for the common cause, that his countrymen thought fit to recal him. A public galley was sent to bring him home; and on the road from the Piræus to Athens, he was met, and welcomed in triumph, by the whole body of citizens. As his fine could not be legally remitted, an equal sum was set aside to relieve him, on pretext of paying his charges, as conductor of the sacrifices to Jupiter the Preserver. But the victory of Antipater over the confederated Greeks at Cranon, in Thessaly, dispelled all the hopes of their cause, and Athens was obliged to purchase peace by the sacrifice of her ten public speakers, among whom Demosthenes was included. On the motion of Demades, a decree passed, condemning them to death. Demosthenes fled to the island of Calauria, and there took shelter in the temple of Neptune. But he was pursued thither by Archias, one of the instruments of Antipater's vengeance, attended by a party of soldiers. Archias, who had been formerly a tragedian, affected to look on his victim with commiseration, and gave him hopes of pardon and safety. Demosthenes coldly and contemptuously replied, "Your acting never affected me, nor can your promises make the least impression." When Archias began to speak in more peremptory terms, "Now," said Demosthenes, "you pronounce the very dictates of the Macedonian oracle, before you had but acted a part. I desire but a moment's respite, that I may send some directions to my family." He then retired, and seemed employed in writing; but when Archias and the soldiers returned, they found him with his head bowed down and covered. Imputing his behaviour to fear, they desired him to rise; but he had swallowed poison, and feeling its deadly effects coming on, he uncovered his head, and fixing his eyes on Archias, "Now," said he, "you need not scruple to act the part of Creon in the tragedy, and to cast out this corpse unburned;" (alluding to a speech in the Antigone of Sophocles, in which Creon orders, that the body of Polynices should be exposed to dogs and birds of prey.) "Oh! gracious Neptune," he then exclaimed, "I will not defile thy temple; while I yet live, I retire from this holy place, which Antipater and the Macedonians have not left unpolluted." He then rose, and desired to be supported, but as he passed the altar, sunk down and expired with a groan.—He died at the age of sixty, and his fickle countrymen regretting his fate, among other honours paid to his memory, erected a statue to him with an inscription, importing, that if his arm could have seconded his counsels, Greece would not have bowed down to Macedon.

The oratorial character of Demosthenes is one of the few points of taste in which the affectation of singularity, or the love of paradox, has hardly ventured to establish a dissentient opinion. The occasional preference of Cicero is established on a predilection for excellence of a different kind, not of a higher degree. The orations of the Roman orator, it seems to be generally agreed, form a larger and more luxuriant treat to the reader; but for giving an idea of consummate pleading, those of Demosthenes are preferred. His style is acknowledged to have a kind of magic, peculiar to himself, even in the Greek language, and which is not to be transfused into translation; in the matter, even when he may be suspected of labouring in the weaker cause, there is a neatness of delusive reasoning, a subtlety of insinuation avoiding assertion, but calculated to infuse belief without pledging the speaker; even his silence, it has been remarked, is frequently pregnant with meaning. That characteristic of eloquence, which Quintilian (from the Greek) calls δεινωσις, is not perhaps to be translated by the single term aggravation—it is in him the power of arraying truth in majestic terror—of alarming and electrifying the attending mind. Even at this day, a reader who, in cooler moments, may well question the general policy of his system towards Macedon, opens one of his Philippics with tacit reflections on the insolence and tyranny of Athens, and the magnanimity of Philip, but as he proceeds, feels his sympathy carried on, to participate in the passions of jealousy, disdain, and impatience for action, which he infuses into the breasts of his audience. The opinions of Cicero and Quintilian on the supremacy of his powers, are in themselves splendid passages of eloquence, which have been often cited. It may be added, that eloquence by no means comprises the sum of his character; Lord Bolingbroke justly remarks, in speculating on the part which he acted in history, that "haranguing was at this time the least part of the business of Demosthenes; and eloquence, neither the sole nor the principal talent, as the style of writers would induce us to believe, on which his success depended. He must have been master of other arts, subservient to which his eloquence was employed; and must have had a thorough knowledge of his own state, and of the other states of Greece, of their dispositions and of their interests relatively to one another, and relatively to their neighbours—to the Persians particularly, with whom he had correspondence not much to his honour,—I say he must have been master of many other arts, and have possessed an immense fund of knowledge, to make his eloquence in every case successful, and even pertinent and seasonable in some, as well as to direct it and furnish it with matter whenever he thought fit to employ that weapon." (*n*)

DENBIGHSHIRE, is an inland county of North Wales. It runs parallel to Flintshire, but it is much more extensive. Although we have denominated it an inland county, yet in one point it just touches on the Irish Sea. On the north-east, it is bounded by Flintshire and Cheshire; on the south-east by Shropshire; on the north-west by Montgomery, Merioneth, and Caernarvon. From Merioneth it is separated by the Bereryn Mountains; and from Caernarvon by the river Conway. The promontory of the Great Ormes-head; however, which is on the eastern side of this river, is in Caernarvonshire. Denbighshire, from Llandwst, on the Conway, to Holt, on the river Dee, measures 36 miles; and from St Asaph to Ysbytty Eran, 19 miles: in its narrowest breadth over the vale of Clwyd, it is but nine miles. The climate of this county, like that of the other parts of North Wales, is of three kinds: that of the vales, the hills, and the mountains. Frequently when it rains in the vallies, sleet falls on the hills, and snow on the mountains. In some parts of the mountainous district of Denbighshire, oats are frequently seen in the month of October quite green. The time of harvest in the vallies is August; on the hills, September, or the beginning of October. The most constant winds are from the east, prevailing during the frosts in winter and the backward cold springs. But the wind blows much more frequently from the west or south-west, though not with such steadiness and constancy. These winds have been observed to prevail nearly three-fourths

Denbighshire.

of the whole year. The quantity of rain that falls on an average, at Llanrwst, is computed to be about fifty inches. Strong loam prevails in the vale of Clwyd, below Ruthin, and in some other parts of the county; but it is by no means common. Above Ruthin, the soil of the vale of Clwyd is a lighter loam, which is also found in the valley of Llanrwst, and in most of the other vale lands. A still lighter species of soil prevails on the slopes of the hills, especially where they have a southern aspect, and have a substratum of limestone. Where the substratum is slate, the soil is *till*, cold, and unproductive. Immense quantities of peat, or moss, are found in the mountainous districts. The principal rivers in Denbighshire, are the Clwyd, Elwy, Dee, and Conway. The tenure of estates is of a mixed kind, between feudal and allodial; they being held either mediately or immediately *in capite* of the king. The size of farms varies much. Scarcely any reach 600 acres; and in general they do not exceed 200, except in the mountain farms, which run to 1000 acres or upwards. The rent, in the vales, is from 20s. to 30s. per acre; in the smaller dales, and on the hilly parts, from 15s. to 20s. The sheep-farms are seldom let by the acre, but they may be reckoned at from 1s. 6d. to 2s. per acre. In the south-east extremity of the county, on the banks of the Dee, there is rich pasture and meadow land, and cheese is made nearly equal to that of Cheshire. In the northern part of the county, many cattle are reared and fed. The vales are chiefly devoted to the growth of corn.

The most celebrated vales in Denbighshire, are those of Clwyd, Llangollen, and Valle Crucis. The first is perhaps the most extensive of any of the kingdom, being 24 miles in length, and about seven in width. It is in a high state of cultivation, and is, moreover, naturally very fertile. Twenty returns of excellent wheat have been produced in it. The river Clwyd runs through it. It is, however, much inferior in picturesque beauty to the vale of Llangollen, and some other vales in this county, though it assumes this character, in some degree, as it contracts beyond this shire, where it is bounded on the Flintshire side by lofty limestone hills, and on the south by the slate rocks of Merioneth, the sides of which are covered with extensive woods. The vale of Llangollen has been much celebrated from the steep banks on the south side of the Dee; by the Oswestry road to Llangollen, the vale is seen to great advantage, the river, winding in elegant courses along the wooded meadows beneath; and the prospect of it from its mouth also, where it sinks into the plain of Salop, towards its commencement, is uncommonly striking; yet some of its most beautiful scenes are greatly disfigured by a formal range of limestone rocks on the north-west side of it. The vale of Crucis extends nearly to Llangollen; it is represented as one of the most charmingly secluded vales that the kingdom can boast of, surrounded by high mountains, the sides and bottoms of which are clad with wood and verdure. The venerable ruins of Valley Crucis Abbey, embowered in trees, add very much to the picturesque effect of this vale. It may be remarked, that the woods near Erthig, in this county, is the only spot in North Wales where the nightingale is heard. There is not much timber in Denbighshire; the best wooded estate is probably that of Lord Bagot's, in the vale of Clwyd.

There are two ranges of mountains in Denbighshire, the Berwyn and the Clwydian range; the former takes its rise near Chirk Castle; its geometrical length is 54 miles, in a straight line 49 miles; its greatest elevation rather more than 3000 feet; it is principally argillaceous, with some chert. Immense quantities of slate are procured from this range. Oernaut, near Llangollen, is considered as the north-eastern commencement of the Berwyn line of slate quarries. A branch of the Ellesmere canal extends from the Pontcysylte aqueduct nearly to this quarry. The slates are more durable than those procured from the quarries near Chirk. The Clwydian range consists of two branches, only one of which properly belongs to Denbighshire; it is from 25 to 30 miles in length, and from 5 to 9 miles broad; it consists principally of shale, semi-indurated whin, and flags for flooring and tomb-stones. This branch is covered with heath or ling; and the hollows abound with peat, so hard and close grained that it exhibits a polished surface when dry. The vale of Clywd lies between the two branches of this range.

Besides slate, lime, coal, and a little lead ore found in Denbighshire, limestone is found at the upper end of the vale of Clwyd; and it composes the Eglwyseg rocks in Llangollen vale. Another branch of this range of limestone hills turns to the north-west, and crossing the collieries and freestone quarries at Ruabon, appears at Minera, near Wrexham. Dark-coloured argillaceous limestone may also be traced from Denbighshire in a south-western direction across Merionethshire; it is much inferior to the white limestone, both as a cement and manure. The lead mines of this county lie on the borders of Flintshire. Near Wrexham, the Minera lead works, which had been wrought for ages, and were considered as nearly exhausted, have been resumed, a fresh vein, five feet broad, having been discovered at the depth of 70 yards. Coal is found above limestone in the eastern part of the county, and very extensive beds between limestone and the sand rocks about Wrexham. At Plas Kynaston, that species of coal, called *cannel*, is found. Granite porphyry in mass, micaceous schistus, and other primitive stratified rocks, as well as serpentine, and hornblende slate mixed with veins and rocks of quartz, are found near Llanrwst.

The principal manufacture of Denbighshire is what is termed *small cloths*; they are thus denominated to distinguish them from the *strong* cloth, which is made near Dolgellen; the pieces of both are of the same length, but the small cloth is about one eight of a yard narrower. It is entirely manufactured within the parish of Glynn, a large tract of country lying between Llangollen and Corwen: in this district there are eleven fulling mills, which dress about 22 webs per week, each web containing about 190 yards. The amount of the annual manufacture is supposed to be L.12,679; the prime cost of the materials L.8475, and the wages of labour L.4204. It is chiefly used for dyeing. The market for Glynn webs is held every Wednesday at Oswestry. Knit stockings and socks are made near Llanrwst. In the neighbourhood of Wrexham there are several manufactories of military instruments; and a large cannon foundry not far from the town. The greatest fair in North Wales is held at this place, commencing on the 23d of March, and continuing to the end of the following week. At Llanrwst there is a great market for stockings.

The Ellesmere canal enters the county of Denbigh at Pulsford, and a branch turns off to the Ffrwd colliery. This canal, which was laid out by Mr Telford, passes over two of the finest aqueduct bridges in the kingdom, viz. those of Chirk and Pontcysylte. The last of these carries the canal over the river Dee, at the bottom of Llangollen vale, and is perhaps the most elegant and splendid structure of the kind in Europe. The piers are of stone, and all the rest of cast iron. The height of the centre piers is about 150 feet, and the number of arches about 13. The Ruabon collieries are connected with it by means of iron rail-roads. On the north side of the Dee, a branch extends to Llangollen; and, as has been already noticed, to the vicinity of the Oernaut slate quarries. The river Conway is navigable for small craft to within two miles of Llanrwst. Near this place is a bridge built by Inigo Jones, consisting of three arches, the middle one of which is nearly 60 feet wide.

There are 57 parishes in Denbighshire, and 6 market towns. The number of acres, by recent survey, is found to be 387,600. It returns two members to parliament. Is partly in the diocese of St Asaph and partly in that of Bangor, and in the province of Canterbury. It pays one part to the land-tax.

The following is an abstract of the population return for 1811:

Inhabited houses	13,078
Families that occupy them	13,703
Uninhabited houses	281
Families employed in agriculture	7,973
Ditto in trade and manufactures	2,283
Males	31,129
Females	33,111
Total population	64,240

The town of Denbigh is pleasantly situated on a limestone eminence, which commands an extensive view of the most beautiful part of the vale of Clwyd. On the summit of this eminence are the fine ruins of its castle. All the streets, except one, are very irregular, and the houses, for the most part, are ill-built. It is governed by two aldermen, a recorder, two bailiffs, and twenty-five capital burgesses. Along with Ruthin and Holt, it sends one member to parliament. It is principally inhabited by tanners, glovers, and shoemakers; and sends a considerable quantity of gloves and shoes to London for exportation. About 50 years ago, a broad cloth manufactory was established here, but it did not succeed. Between this place and Ruthin, nearly 13 acres of lavender are generally grown, which is distilled and sent to London. The population of the town of Denbigh in 1811, was 2714. See Bingley's *North Wales*; Aikin's *Tour through North Wales*; Davies' *View of the Agriculture of North Wales*; and the article INLAND NAVIGATION, for drawings and descriptions of the aqueduct bridges of Chirk and Pontcysylte. (W. S.)

DENDERA, or TENTYRA. See CIVIL ARCHITECTURE, vol. vi. p. 573; Plate CXLVIII.; and Plate CLII. Fig. 2. See also TENTYRA.

DENDERMOND, or TERMONDE, a town of France, in the department of the Scheldt, is situated at the junction of the rivers Scheldt and Dender, by the last of which rivers the town is traversed. The town is surrounded by marshes and fine meadows. It has two parish churches, one of which is collegiate; a college, and two convents of men and four of women. The parish church of Notre Dame contains an excellent picture of the adoration of the Shepherds by Vandyck; and in the church of the Capuchins is another of a dying Christ, which has been esteemed the *chef-d'œuvre* of the same celebrated artist.

The position of this place is very strong, as the surrounding country can readily be laid under water. Its citadel and fortifications are likewise strong; and it is considered as a place of great importance in expediting or facilitating the communication between Gand and Antwerp. The principal manufactures of Dendermond, are fustains and linen, and some imitations of Indian stuffs. The surrounding country produces corn, hemp, and flax, and is remarkable for its excellent breed of horses. The population of the town is about 5028. East Long. 4° 20′, and North Lat. 51° 3′. See Descamps *Voyage Pittoresque de Flandre*. (*j*)

DENDROBIUM, a genus of plants of the class Gynandria, and order Diandria. See BOTANY, p. 315.

DENDROMETER, from δενδρον *a tree*, and μετρον *a measure*, is a name which was at first given to a trigonometrical instrument, invented by Messrs Duncomb and Whittel, for measuring the trunk, the branches, and the height of a tree, without coming near it. This instrument, and a variety of others for the same purpose, are founded on the principle of measuring the angles which the same object, or the same part of an object, subtends at the extremities of a base actually included in the instrument. We do not conceive any of these instruments of sufficient importance as dendrometers, to deserve a separate description in this article. We shall therefore content ourselves with a few references, which will enable our readers to judge for themselves. See Duncombe and Whittel's Description of their own Dendrometer; *Transactions of the Society for the Encouragement of Arts, Manufactures, and Commerce*, vol. 25, for an account of Mr Broad's Gauge or Measure for timber; and the *Repertory of Arts*, vol. ii. p. 238, for an account of Mr Pitts' Dendrometer. The description of a variety of new trigonometrical instruments, which may be employed as dendrometers, and for analogous purposes, will be found in Brewster's *Treatise on New Philosophical Instruments*. Edin. 1813. See MICROMETER. (*o*)

DENEKIA, a genus of plants of the class Syngenesia, and order Polygamia Superflua. See BOTANY, p. 300.

DENIS, ST. See DENYS, ST.

DENMARK.

General view.

The kingdom of Denmark is composed of several islands, as well as of part of the Continent of Europe. Of the islands, Zealand, in which the capital of the kingdom stands, is the largest. The soil is sandy, but fertile both in grain and pasturage; and the face of the country is agreeably diversified with woods and lakes. Funen or Fioni is the second in extent, but the first in fertility; it is higher ground than Zealand, from which it is separated by an arm of the sea, called the Great Belt, so named to distinguish it from the Little Belt, that divides it on the other side from Jutland. This island is particularly celebrated for the richness of its pasturage; nor are those parts of it which are arable less productive. The islands of Laland and Falster are next in point of size; the latter is abundantly productive of fruit; and both are celebrated for the excellent quality and large crops of wheat which are grown in them. The other isles require no particular notice. The head of that long peninsula, which is bounded on the west by the Ocean, on the north and east by the gulf called the Categate, and on the south by Holstein and part of the Baltic, is called Jutland, and forms the largest and most fertile of all the provinces of the kingdom of Denmark. It raises grain, not only for its own consumption, but also, in a great measure, for the support of Norway. A great number of small cattle are likewise bred in this province, which are sent into Holstein to be fattened for the markets of Amsterdam, Lubeck, and Hamburgh. To the south of Jutland lies the province of Holstein, which is bounded on the west by the Ocean and the Elbe, on the east by the Baltic sea, and on the south by part of the Electorate of Hanover. Holstein possesses a soil still more fertile than that of Jutland, and is supposed to furnish more excellent fat cattle, and provisions of all kinds, in proportion to its size, than any other province of Europe. Its climate is much more temperate and agreeable than that of any other part of the kingdom of Denmark. Norway is bounded on the north and west by Lapland and the Ocean, and on the south and east by the same Ocean and Sweden. The interior of Norway is entirely composed of mountains, covered with woods; it is cold, disagreeable, and uncultivated; on the sea coast, however, there are considerable tracts of fertile soil. To the north of Norway, Lapland is situated, inhabited by a race of people very different in figure, countenance, language, and manner of living, from the people of Norway. Such are the parts of the kingdom of Denmark, which lie contiguous to each other. Iceland, which lies between the 63d and 67th degree of north latitude, and between the 15th and 23d degree of west longitude, first inhabited by a colony of Norwegians, afterwards united to the crown of Norway, and thence passing under the power of Denmark, is a very large island, almost entirely covered with rocks, high mountains, and volcanic remains; these, united to the extreme coldness of the climate, render it a comfortless habitation for a very thin population. From Iceland a colony was sent to Greenland; but the eastern coast, on which it settled, having been since blocked up by the ice, this colony has been sought for in vain. Formerly the Norwegians possessed the islands of Orkney and Shetland; and the Danish monarch still retains the Faroe isles, seventeen in number, producing a little barley, and affording excellent pasturage for a few sheep. The small possessions which belonged to Denmark in the East and West Indies, have been captured from them by Britain, during the French revolutionary war.

Part I. HISTORY OF DENMARK.

History.

Definition.

Much doubt and conjecture have arisen respecting the etymology of the name of Denmark. Saxogrammaticus, the historian to whom we are principally indebted for our knowledge of the early history of this kingdom, is of opinion that Denmark signifies the kingdom of Dan, a monarch who is supposed to have reigned 1038 years before Christ. By others, it is alleged, that the river Eyder, which separates Denmark proper from Germany, was anciently called Dana, and that the county to which the name of Jutland is now given, was, from that river, named Danea or Denmark. Another conjecture is, that Denmark is derived from the Teutonic words *dane* or *thane*, a prince or lord, and *mark*, a boundary; hence, signifying a frontier country, under the dominion, or confided to the protection, of a thane. But the most probable conjecture is, that Denmark is derived from the *Danes*, the inhabitants, who are mentioned under this appellation in the sixth century, and *mark*, a boundary. What is the etymological meaning of *Dane*, as applied to a people, it is difficult to conjecture.

The first notice which we possess respecting the inhabitants of Denmark, is derived from the Roman historians. The ancient Cimbria seems to have comprehended Jutland, Holstein, and some parts of Lower Germany; and in some districts of Holstein, it is said that the people, even to this day, preserve the name of Cimbri. The irruption of the Cimbri and Teutones in the year of Rome 640, into the Roman territories, is well known; as well as their almost total destruction by Marius. It is, however, a curious and interesting question, whether these Cimbri were a Celtic or a Gothic people; as hence we may be enabled to determine whether, at the period of the irruption, Denmark was inhabited by the same race of people who possess it now. In support of the opinion that the Cimbri were a Celtic race, it is urged that Cimri is the name given to that division of the Celts who inhabit Wales; and that even to this day, the Welsh distinguish themselves by this appellation. This argument certainly possesses great weight; but in support of the opinion that the Cimbri were a Gothic people, it may be stated, that from history it appears they made the irruption into the Roman provinces along with the Teutones, undoubtedly a people of Gothic descent; and as the Celts and Goths differed essentially in manners, customs, dispositions, and more particularly in language, and as, moreover, the former having been subdued by the latter, and ex-

Cimbri.

History.

pelled from their habitations, cannot be supposed to have been on very friendly terms with the latter, nor to have been regarded by them with much respect, it is hardly to be supposed that they would unite in an expedition of such a magnitude and duration. It is not easy to conceive how the Cimbri, if they were a Celtic race, should have been left in possession of the Cimbric Chersonesus, at a period when we know that the Gothic tribes had poured round that country in all directions, and when the Teutones had actually settled themselves to the south and east of it. It may be further mentioned, in support of the opinion, that the Cimbri were a Gothic people, that the names of most of their leaders, as given by the Roman historians, are evidently of Gothic construction and etymology. The only objection to this hypothesis arises from the circumstance that they were called Cimbri, but this objection may be plausibly, if not satisfactorily, obviated, by supposing that the Romans gave them this name from the county which they inhabited, in the same manner as modern historians give the name of Americans to all who inhabit that quarter of the world, without meaning to imply that they are of the aboriginal race. In the time of Tacitus and Ptolemy, the Chersonese still retained the appellation Cimbri, though, from the testimony of these authors, it was entirely inhabited by Gothic tribes; according to Tacitus, those were the Angli, Varini, Eudoses, Suardones, and Nuithorus. In the island of Zealand, he places the Suiares. Ptolemy gives different appellations to these tribes, but the authority of Tacitus seems entitled to more credit.

The Cimbri were a Gothic people.

Woden or Odin.

In treating of the ancient history of Denmark, the tradition respecting Woden or Odin, must not be entirely passed over in silence. According to Snorro, an ancient historian of Norway, and Torfaces, an Icelandic writer of great erudition, Odin lived in the time of Pompey, and reigned in those districts to which Mithridates fled when defeated by the Roman general. Odin was persuaded by the defeated monarch to assist him in his distress; but being unable to resist the discipline and skill of the Romans, he was compelled to leave his own country along with his followers. How he contrived to fight his way, and to subsist during his long flight from the neighbourhood of the Black Sea till he reached the Scandinavian regions, is not known, nor even conjectured. He is said first to have reduced the island of Funen, and there to have laid the foundation of a town, which, from himself, is called Wodensee, or Odensee. From Funen he passed to Sweden, which he also subdued; and to which, after having made an equally successful expedition into Norway, he returned, when he died. Though much obscurity prevails respecting the era of Odin, and much fable is undoubtedly mixed up with the traditionary account of his origin, adventures, and conquests, yet there can be no doubt that such a person existed, and that he came from some part of Asia, and established himself in Scandinavia.

Schiold, A. C. 60.

But to return more immediately to Denmark. According to the Danish Chronicles, Schiold, the first king of this country, reigned about 60 years before Christ; and he was succeeded by eighteen kings, to the time of Ragner, surnamed Lodbrog, who began his reign A. D. 750, and who, in his attempt to invade England, was made prisoner and put to death. The Danes, at this period, were very formidable to most of the nations of the north and middle of Europe. For 200 years they spread terror on the coasts of England, and at last conquered the whole kingdom. They likewise made incursions on the coasts of Scotland, Ireland, Livonia, Courland, and Pomerania. And it is said, though on doubtful authority, that they even set fire to the palace of Charlemagne, at Aix-la-Chapelle, and carried their ravages into Spain and Italy. They were enabled to effect these conquests, and to carry on these depredations, by their expertness and skill as sailors. The greatest part of the people were from their childhood brought up to a maritime life. Their vessels were always well provided with arms, and all the men were taught to swim. A very striking proof of the attention which the government at this period paid to the establishment of a maritime force, is exhibited in the manner in which the lands were divided in Denmark and Norway. Every division took its name from the number of vessels which it was capable of equipping; and in some places these names are still in use.

Lodbrog A. D. 750.

History.

Surm, A. D. 920.

On the death of Ragner Lodbrog, who was the last of the powerful princes, under whose dominion the three kingdoms of Denmark, Norway, and Sweden were united, his sons divided these territories, and Denmark again acknowledged a separate king. Soon after this period, the more certain history of Denmark commences, with Surm, or Sormo, A. D. 920. It is not known, however, whether he was descended from a native race, or whether he was of Swedish or Norwegian origin. The confusion which, before the reign of this sovereign, is found in the Danish history, is plausibly supposed to have arisen from the circumstance, that Denmark, in fact, was never completely, or for any length of time, under the dominion of one prince; but being divided among two or three, one historian writes the history of one prince, and another of another prince; all representing their heroes as sovereigns of the whole of Denmark. Sormo united, in reality, as well as nominally, the whole of Denmark under one sovereign. He was succeeded in 945 by Harold Blaataud, his son. This prince not only made war in France and England, but attacked part of Germany, during the absence of the Emperor Otho. On his return, however, the Danes were expelled with great slaughter, and followed into Jutland, where Harold was compelled to solicit a peace, which was granted him, on condition that he and his son Swane should be baptized. In 985, Swane succeeded to the throne. From the circumstance of his having been baptized, at the command of Otho, he is sometimes called by the Danish historians, Swane-Otho. This sovereign is well known in English history, by his invasion of England.

Harold Blaataud, A. D. 945.

Swane, A. D. 985.

Canute the Great, A. D. 1017.

A new epoch in the history of Denmark commences with the reign of Canute the Great, who succeeded his father Swane, on the thrones of Denmark, England, and Norway, (See CANUTE.) The conquest of this last country had been begun by his father, and was completed by himself. The reign of this prince is principally distinguished by a code of laws, which he made for Denmark, under the title of the Laws of the Court. The chief object of those laws was the regulation of the differences which were continually arising between the officers of the army and those of the court, which were terminated by duel, a practice which Canute thought should no longer be permitted or continued in Denmark, after it had been converted to the Christian faith. Canute gave great offence to the Danes, by fixing his abode in England, and only occasionally visiting Denmark, and by filling all the places of trust in this kingdom with Englishmen. The discontent at last became so general and loud, that he thought it prudent to pass a whole winter in Denmark; while there, he employed himself in subduing part of Norway, which had revolted under

History.

Olaus, one of its native princes. Canute was successful in this enterprize, but afterwards returning to England, and leaving the sovereignty of Denmark to his son Hardy Canute, Magnus, the son of Olaus, not only reconquered Norway, but compelled the Danish monarch to enter into a treaty with him, which gave to the survivor the estates of the other, in case he should die without male heirs. On the death of Hardy Canute without male heirs, Magnus became King of Denmark, and England shook off the Danish yoke.

Hardy Canute.

Magnus.

Swein.

Nothing remarkable happened in the reign of Magnus, nor in that of Swein his successor. The latter reigned only two years, and was succeeded by his brother Canute the Fourth. The piety or the weakness of this prince, induced him to exempt the clergy from the civil jurisdiction of the state; to raise their rank, and increase their stipends; and at last to attempt to establish the usage of paying tithes. This, however, enraged the people, over the great body of whom he ruled with great severity; and Canute persevering in his determination, levied the tithes with such rigour, that a rebellion ensued, and he was slain as he was kneeling before the altar. Canute was succeeded in 1086 by Olaus the Second, during whose reign nothing remarkable occurred. When he died in 1095, the states elected his brother Eric the First to be king, who renewed the ancient usage of consulting the states before war was declared, or any great enterprize undertaken. After having reigned eight years, this prince died in the isle of Cyprus, while on a pilgrimage to Jerusalem. For upwards of 50 years afterwards, during the reigns of Nicholas, Eric the Second, Eric the Third, and Swein the Third, Denmark was a continual scene of confusion and bloodshed, occasioned principally by the contests between the clergy, the nobility, and the sovereigns.

Canute IV.

Olaus II. A. D. 1086.

Eric I. A. D. 1095.

Valdemar the Great, A. D. 1157.

In 1157, another epoch in the history of this kingdom commences with the reign of Valdemar the Great. He defeated the Wouds or Slavonic inhabitants of the southern shores of the Baltic; subdued the isle of Rugen, and gained possession of great part of Pomerania. According to the ancient chronicles of Pomerania, he founded the town or the castle of Dantzic, which was originally called Danskwic, or the fort of the Danes. The same chronicles relate, that Valdemar made war on a prince, whose territories lay along the banks of the Vistula, called Sobieslas. In 1169, he subdued Courland; and he was enabled, by the friendship and assistance of the Emperor Frederic Barbarossa, to retain all his conquests, except the territory on the Vistula, which, on his return to Denmark was re-occupied by Sobieslas. The reign of Valdemar is not more celebrated in Danish history for the conquests which he achieved, than for the laws that he enacted, and for the tranquillity and happiness which his wisdom and firmness established among his subjects. He revised and published two codes of laws, one called the Laws of Scania, and the other the Laws of Zealand; these related entirely to civil matters. He also drew up ecclesiastical laws for these provinces. Those laws, in conjunction with the code of Lapland, published by Valdemar the Second, are the source from which the present laws of Denmark are derived; and in their enactments they are well calculated, if properly administered, to protect the rights and property, and secure the tranquillity of the people.

Canute VI. A. D 1195.

Valdemar died in 1182, and was succeeded by his son Canute the Sixth, who, in the year 1195, caused a muster to be made of all the men fit to bear arms in his dominions; he at the same time issued orders for each province to supply its proportion of shipping, and by this means 670 vessels were equipped and manned. In his reign, part of the Duchy of Holstein, and the cities of Hamburgh and Lubeck, were annexed to the Danish territory, and he received the homage of the Duke of Pomerania and the Prince of Mecklenburg. This prince first admitted the feudal law into Denmark, which soon became the means of reducing the great bulk of the people to a state of the most abject slavery. He paid great attention to commerce, and particularly encouraged the herring fishery. A curious and interesting picture of the Danes, at this period, is given by Arnold, the author of the Slavonian Chronicle. In consequence of their commerce with the Germans, he informs us, "the Danes, who were formerly clothed as sailors, are now clothed in red, and in stuffs of other colours, and even sometimes in purple and fine linen." He describes the herring fishery as very productive and lucrative, bringing into the country, "gold, silver, and all other precious things." "Moreover, Denmark is also filled with excellent horses, which is owing to the great fertility and goodness of their pasture, so that they are distinguished in war by their cavalry and marine." According to the same authority, at this time it was usual for the nobles of Denmark to send such of their sons, as they designed for an ecclesiastical life, to Paris, to be instructed in literature and polite learning, in consequence of which, this kingdom had made a considerable progress in many of the sciences. In the reign of Canute the Sixth, several Danish historians lived, particularly Suene Aggesen, who has given an abridged history of his own country from the foundation of the government, written in correct, and rather elegant Latin.

History.

Valdemar II. A. D. 1202.

Canute the Sixth died in 1202, and was succeeded by his brother Valdemar the Second. His first object was to obtain from the Emperor of Germany a sanction to his claims on the countries that had been conquered from the empire during the two preceding reigns: having accomplished this, he invaded Esthonia, not so much for the sake of conquest, as in order to convert its savage and idolatrous inhabitants to the Christian faith. At first he was unsuccessful; but afterwards, the zeal and enthusiasm of his troops having been excited and directed by the clergy, who accompanied the expedition, the Esthonians submitted to him. By this conquest the Danish power extended both to the south and east shores of the Baltic. In consequence, however, of his having been surprised and carried off, while engaged in the chace, by a prince of Mecklenburgh, the conquered countries revolted; and before he regained his liberty, they had established their independence. He was defeated in 1227, by the Germans, in an attempt he made to regain Holstein; and died, stripped of most of his conquests, in 1242. This prince is much celebrated for the attention which he paid to the laws of Denmark: the code of Jutland has already been mentioned. It was drawn up in consequence of the confusion which prevailed in many parts of the kingdom: several new laws, or modifications of the old laws, had been introduced from Germany, by the doctors and advocates who had studied there, and the people were at a loss to know what was legal, and conformable to the ancient laws. To remedy this evil, Valdemar convoked a general assembly of the states at Wordingburgh in Zealand, and by this assembly the Jutland code was drawn up; this code, like our magna charta, rather gives a regular and fixed form and authority to the ancient customary and unwritten laws, than creates any new ones. In this code, particular attention

Dies, A. D. 1242.

History.

was paid to the maritime strength of the country, the whole of which was divided into small districts; each of these was to build and equip one ship in time of war, and furnish it with provisions as long as the king should require its service. The progress of the feudal tenure is distinctly marked by several of the enactments of this code. In the maritime districts were many free farms: but the number of these was much reduced by the permission that Valdemar gave to his favourites to purchase them, and to form them into hereditary manors: hence arose those nobles, who afterwards, in conjunction with the clergy, oppressed the people so cruelly and unmercifully, and limited and rendered insecure the power of the sovereign himself. The principal new regulations, which Valdemar introduced into the Jutland code, respected the abolition of the trial by ordeal, and the substitution of the *canonical purgation*, on the oath of one of the parties, substantiated by the oaths of eleven of his relations. The trial by jury, exactly as it is practised in England, was also established by him; but it is doubtful whether this mode of trial was followed for any length of time, and it certainly cannot now be traced in the present practice or laws of Denmark.

Eric. By the will of Valdemar, the crown of Denmark was left to his oldest son Eric, and the duchy of Sleswick to his second son Abel. The former entered into a war with the princes of Holstein, in which he solicited the assistance of his brother Abel, but Abel hired assassins,
Abel. who murdered him. After this, Abel succeeded to the crown, which, however, he did not long possess, as his subjects rebelled against him, and he was slain in battle,
A. D. 1252. in the year 1252. Although the private character of this sovereign was very bad, yet when he came to the throne, he discovered great wisdom and regard for the happiness of his subjects, in several of his regulations and laws: he re-established the custom of holding a general assembly of the states every year, which had been long neglected; and in many respects he improved upon the Jutland code.

Christopher I. Christopher the First succeeded Abel: his whole reign was a scene of confusion and civil war between him and the clergy; the disturbances continued with little or no intermission during the reign of his son, Eric the Fifth, who succeeded to the throne, when he was only ten years old, and reigned twenty-seven years.
Eric V. He compiled the code called *Birkerett* from *Birketten*, the name of the new tribunals, which were instituted by it. At this period the clergy and nobles treated the judges and governors whom the king sent into their provinces as greatly their inferiors; nor would they suffer them to exercise any jurisdiction over their lands, or even to hear or settle the complaints of their farmers, whom they considered and treated, rather as their own proper subjects than as the subjects of the king. As Eric found it would be impracticable to destroy the powers and assumed privileges of the clergy and the nobles, he endeavoured to regulate them by his new code, by which he granted to the lords of fiefs their proper jurisdiction, and laid down rules for the guidance and information of the judges in the administration of justice. But his views were frustrated; the nobility regarded more that part of the code which acknowledged and legalized their power, than that part which taught them their duty towards their vassals, and the code of birkerett, especially after the changes it underwent, in the time of Christopher of Bavaria, may be considered as having consummated and sealed the slavery of the people of Denmark. Eric the Fifth was succeeded by his son Eric the Sixth, whose reign also exhibits a continued scene of confusion and civil wars. During the short intervals of peace and tranquillity which he enjoyed, he applied himself to the formation of a code of feudal laws for Livonia, at that time a fief of the crown of Denmark; and he confirmed and extended the privileges which his predecessors had granted to the inhabitants of Lubeck and Rostock. He also directed his attention to the laws of his own country, collecting and publishing the laws of Zealand in six books; and depositing, in a place of safety, all the public acts, documents, and other papers, which might be of use in forming a complete history of Denmark.

History. Eric VI.

Christopher the Second succeeded to the throne, on the death of his brother Eric. In order to engage the states to confirm him in his power, he agreed to grant them great privileges: when he received the crown, he bound himself by an oath, to confirm and extend the privileges of the clergy; not to permit them to be accused before lay judges, on any pretext, or for any cause whatever; not to tax them; nor to arrest, banish, or deprive them of their property, except by the express order of the pope: to the nobility he promised, that he would grant them the power of condemning their vassals; and exemption from carrying arms out of the kingdom: he also bound himself to destroy all the fortresses in Jutland except three, and to grant permission for all those to return, who, in the preceding reigns, had taken up arms against their legitimate sovereigns. This extension of the powers and privileges of the clergy and nobility was resisted by the towns, which now began to feel their importance; they sent deputies to the diets; and even the peasants or farmers, who possessed small estates, now began to form a separate class. The aim and efforts of the towns and communes, were directed not only against the encroachments of the clergy and nobility, but also towards compelling the king to extend their own immunities and privileges. He was obliged to promise them, that commerce should be free, and that no tax should be laid upon it, except in cases of the greatest necessity, and then, only by the consent of the senate; that an assembly of the states should be held every year at Nybourgh; that the laws of Valdemar should be recognized as the laws of the whole kingdom; that whenever any person considered himself as unjustly dealt with by the inferior tribunals, an appeal should lie to the general assembly of the states; and that no new law should be made, but in the general assembly, and by their consent. Christopher had thus stripped himself of all real authority, and soon became sensible that he was in fact the slave of the clergy and nobility: his situation was rendered still worse by his profligacy and extravagance, so that after having mortgaged several of his provinces to his own vassals, he resolved, notwithstanding his oath, to attempt to raise taxes, without the consent of the states. He accordingly suddenly laid on a general tax on all his subjects: the nobility were to have a tenth of all their revenues, and the clergy and commons were equally charged, in proportion to their funds. The whole kingdom was immediately in a state of open and violent rebellion: the clergy expressly told him, that as he had disregarded his oaths, they should no longer consider themselves bound to obey him as their sovereign. Christopher, intimidated by this menace, and alarmed at the rebellion of his subjects, desisted from his project, but only to adopt another, equally unjust and hurtful to his real interests: he employed force to recover the lands which he had mortgaged, and refused

Christopher II.

to pay the debts which his brother or himself had contracted. This conduct irritated and inflamed the nobility, and a civil war, which continued the whole of his reign, ensued. His situation was rendered still more distressing and perilous, by the death of Eric, Duke of Sleswick, of whose son, being under age, Christopher claimed the guardianship: his claim was opposed by the Earl of Holstein, maternal uncle to the young prince: a war ensued between them, but Christopher was defeated in a battle near Gottorp. His defeat encouraged the rebellion of his subjects; who issued a solemn decree, that he, as well as his eldest son Eric, had forfeited the crown, and soon afterwards proclaimed the young Duke of Sleswick King of Denmark. This arrangement, however, was soon set aside; the new sovereign returned to his own duchy; his maternal uncle took possession of Jutland and the island of Funen; the other islands in the Baltic were divided among the discontented nobles; and Schonen, Hallund, and Blekingen, were reconquered by Sweden. The only part of the Danish dominions, which continued to recognise Christopher, was the province of Zealand, to which, after his defeat near Gottorp, he returned from Mecklenburgh, whither he had fled, and where he soon afterwards died.

Duke of Sleswick claims the crown.

On his death, the young Duke of Sleswick again claimed the crown of Denmark. His claim was at first admitted, till the assassination of his maternal uncle, who, in fact, exercised the regal power. Soon after this event, the nation, discontented and exasperated at the ascendency which the House of Holstein had gained, invited Valdemar, the youngest son of Christopher, to the throne; Eric, the oldest, having died before his father. This prince was assisted by the Emperor of Germany in the recovery of his hereditary dominions; and in a treaty of peace, which was concluded between him and the Duke of Sleswick, by which the latter renounced the crown, but kept the duchy as a hereditary fief; and, by a treaty with the king of Sweden, the provinces which had been wrested from Denmark during the reign of Christopher the Second, were restored. So far, the reign of this prince was prosperous; but the scene soon changed. The Hanse Towns, grown rich and powerful by commerce, declared war against him, and carried their ravages into the very heart of Denmark. Being assisted by some of the neighbouring powers, they compelled Valdemar to conclude a peace on their own conditions. As soon as peace was restored, he applied himself to regulate the internal state of his kingdom; but, before he had reduced his plans into practice, he died in the year 1378.

Valdemar invited to the throne.

A. D. 1378.

This prince had two daughters; the oldest was married to a Duke of Mecklenburgh, and had a son, who, on the death of his grandfather, assumed the title of king of Denmark. The second daughter, Margaret, was married to Haquin, king of Norway, and had a son, called Olaus. This son, the states of Denmark chose to be their king; and, on the death of Haquin, he also succeeded to the throne of Norway, and to the pretensions which his father had to the kingdom of Sweden. When Olaus ascended the throne of Denmark, he was only ten years of age; the states therefore declared Margaret regent during his minority; and, on his death, seven years afterwards, they chose her for their sovereign. Before, however, the states of Denmark agreed to elect Olaus, in preference to the son of the oldest daughter of Valdemar, and subsequently to fix Margaret on the throne, they took care to extend and secure their laws, liberties, and privileges. The senate of Norway followed the example of the states of Denmark, both in the election of this princess, and in fixing the terms on which they agreed to choose her as their sovereign. They also decreed, that the sceptre should pass to Eric, the nephew of Margaret, at that period an infant of five years old. Being thus securely fixed on the thrones of Denmark and Sweden, this princess, who was endowed with a most ambitious spirit, and with talents and enterprize amply sufficient to attain and secure whatever her ambition prompted her to desire, turned her thoughts towards Sweden. This kingdom was a prey to domestic convulsions. The right of succession to the crown undoubtedly belonged to her husband Haquin, as son of the last king, and to his heirs; but to the exclusion of them, Albert the Second, Duke of Mecklenburg, had been elected king. This prince, seated on a throne to which he had no title, had not policy sufficient to establish himself in it, by acts of justice, or even of clemency; on the contrary, he rendered his authority unstable by his oppression and tyranny. Margaret did not fail to take advantage of this state of things; she encouraged and extended the divisions which had taken place between him and his subjects. The clergy of Sweden were entirely in her interest, and the mass of the people were won by her generosity. She did not, however, trust to these circumstances alone; she formed a love intrigue with one of the Swedish nobility, and by this means gained many of them over to her party. Thus, supported by the clergy and a great portion of the nobility and the people, the chance of Albert in opposing her seemed desperate. He resolved, however, to attempt it: a great part of the Swedish army still adhered to him; and he received assistance from Henry of Mecklenburg, and other German princes, who were jealous and afraid of Margaret's elevation to the throne of Sweden. The Swedish malcontents, in the mean time, had put most of the fortresses into her possession, and made her a formal offer of the crown. This she accepted, on the condition that it should be made hereditary; to which condition, after some delay and hesitation, the malcontents acceded. Of all the provinces of Sweden, Margaret depended most on Dalecarlia; the inhabitants of which, warlike and intrepid, had come forth almost unanimously in her favour; and, in order to supply her with resources to carry on the contest with Albert, they put her in possession of the copper mines, notwithstanding they had been mortgaged to the princes of Holstein. Albert still had hopes, that though the malcontents had offered the crown to his rival, the Swedish senate would not go so far; he could not expect that they would support him; all he looked for, and reckoned upon, was their neutrality. In this, however, he was disappointed; perceiving that the voice of the nation was decidedly for Margaret, they ratified the treaty which she had concluded with the deputies of the malcontents, and acknowledged her queen of Sweden, Denmark, and Norway. Albert now determined to appeal to arms; and, collecting a numerous body of troops, he prepared to take the field. Nor was Margaret idle; she marched a large army, composed of Danes and Norwegians, under the command of four generals, to join the disaffected Swedes. As soon as the junction took place, they advanced against Albert, and came up with him at Falkoping, where an obstinate and furious battle was fought. Victory was for a long time doubtful; but the good fortune of Margaret at last prevailed, and the army of Albert was almost entirely cut to pieces. As

Olaus.

Battle of Falkoping.

Albert taken prisoner.

soon as he saw the fate of the day, he fled from the field of battle, but was taken prisoner in the pursuit, along with his son Eric, and several of the German princes who had supported him. He was immediately confined in a strong fortress on the borders of Norway, where he remained seven years. Although this victory was great and splendid, it was not decisive. The Swedes, who still adhered to Albert, were soon joined by fresh German forces, and made themselves masters of Stockholm; while the Prince of Mecklenburg ravaged the coasts with a powerful fleet, and took possession of the Isle of Gothland. These events, however, only retarded the accomplishment of Margaret's designs and hopes. The Swedish and Pomeranian cities came over to her; and, in 1391, she ruled over the whole of the kingdom, with the exception of Stockholm, which city did not yield to her till the year 1394.

Eric elected the successor of Margaret to the crown of Sweden.

Having now completely succeeded in her favourite project of uniting the three kingdoms of the north under one head, she resolved, if possible, to procure the election of Eric of Pomerania, to be her successor to the throne of Sweden, as he had been already declared to the thrones of Denmark and Norway; for this purpose she assembled the Swedish states at Upsal, and in a long and eloquent speech, pointed out the numerous and great advantages that would result from the union of the northern kingdoms; and promised them, if they would accede to her wishes, the security of their privileges, the abolition of extraordinary taxes, and the redress of all their grievances. No opposition was made to her request, and Eric was elected her successor to the throne of Sweden.

Union of Calmar passed A. D. 1397.

In the month of June 1397, Margaret convoked the states of the three kingdoms at Calmar, where the law, called the union of Calmar, was passed. As this law was the cause of a long war between Denmark and Sweden, it will be proper to notice its principal clauses. The grand and leading proposition laid down in this law, was, that the union of the three kingdoms under one monarch, should be a fundamental and irrevocable law. In order, however, to secure to each kingdom its peculiar rights and privileges, it was expressly declared, that "the sovereign should govern the kingdom of Denmark according to the laws and customs of Denmark; and those of Sweden and Norway according to their respective laws and customs." If any person is justly banished from one of the kingdoms, he shall be equally so from the two others; and no person shall assist or defend him; but, wherever he shall be followed and cited, they shall proceed to judgment against him, according to law." "If our lord the king shall enter into any agreement or treaty with any foreign power, in which of the kingdoms soever he shall then reside, he, and the senate who are then with him, or some deputies from each kingdom, shall have the power to contract, in the name of the three kingdoms, every thing which shall be judged the most honourable and advantageous for the king and the three kingdoms." It was likewise ordained, that if any sovereign had more than one son, one only should be declared and elected king of the three kingdoms, and the others should hold fiefs; and if the king should die without any children, then the senators and the states-deputies of the three kingdoms, in concert, should elect him whom they believed before God most worthy and most capable. Such are the principal articles of the famous union of Calmar; by accomplishing which, as well as by the whole of her political conduct, Margaret has obtained from posterity the appellation of the "Semiramis of the North." This great princess died suddenly in 1412, and left Eric in peaceable possession of the three northern crowns.

Eric succeeds to the crowns of Denmark, Norway, and Sweden, A. D. 1412.

Soon after his accession to the throne, he was engaged in a war with the Count of Holstein, and with the Hanse Towns. Not being a sovereign of much talent or enterprise, he was totally unable to carry on these wars, and attend to the affairs of Sweden at the same time. The Swedes soon manifested symptoms of discontent; they justly regarded themselves as inferior, in the treatment they received from the king, to his Danish and Norwegian subjects. Their disaffection and discontent were soon evident to all but Eric, whose inattention or obstinacy were such, that he could not be persuaded to adopt such measures as would have ensured the tranquillity of Sweden. The Swedes were still farther exasperated by the taxes he levied on them, in order to prosecute his war with the Hanse Towns. In this war they conceived themselves to have no interest or concern; and therefore they thought, they should not to be taxed to support it. They had still another source of discontent: Eric had appointed Danish or German governors to nearly all the provinces and fortresses of Sweden. This of itself gave them umbrage, and was expressly contrary to the spirit of the union of Calmar. These foreign governors oppressed and tyrannized over the people; and, when complaints against them were laid before the king, he treated them with neglect or contempt. After patiently enduring their grievances for some time, the Swedes broke out into open rebellion. Eric was now seriously alarmed, and, having made peace with the Hanse Towns, he requested their intercession with his rebellious subjects; this they granted, on condition that a diet, composed of the deputies of the three Estates, should be held at Calmar. The diet was accordingly held on the 27th of July 1436, when the Swedes agreed solemnly to renew the union; the king, on his part, binding himself to respect their privileges, and not to entrust any of their strong places in future to the care of foreigners. Eric, however, was either not sincere, or he had not talents sufficient to perceive and follow his real interests; for, soon after the renewal of the union, he exercised a most tyrannical sway, not only over Sweden, but even over the Danes and Norwegians. This conduct united them all against him; and he was soon compelled by the Danes to surrender the crown. During the reign of this sovereign, the famous fortress of Elsinore was built. The principal object in erecting it was to check the commercial and maritime power of the Hanse Towns, with whom Eric was then at war. These towns soon felt the restrictions which this fortress, commanding the passage of the Sound, laid on their commerce; and, in revenge, they ravaged the coasts of Denmark and Norway. When peace, however, was concluded, they agreed to pay the tribute which Eric fixed for the passage of the Sound.

Diet of Calmar, A. D. 1436.

Eric compelled to surrender the Danish crown.

Christopher of Bavaria elected king of Denmark, and of Sweden.

The Danes, having compelled Eric to abandon the throne, elected Christopher of Bavaria, his sister's son, to be their king. After he had taken possession of the crowns of Denmark and of Norway, he directed his attention and his schemes towards Sweden. The Swedes, at first, appeared unwilling to elect him; but at last, partly by intrigues, and partly by the privileges granted or extended to them, they chose Christopher king. He was crowned at Copenhagen, which city he made the royal residence, and the capital of Denmark, instead of Roschild, which had previously enjoyed those privileges. The first object with this sovereign, after

History.

he was securely seated on the throne of the three kingdoms, was to revise the laws of Denmark; many of them had become obsolete, inapplicable, or insufficient; into others, many abuses had crept, either in their interpretation or administration; and the changed state and circumstances of the kingdom and of the times, required some new enactments. The plan he followed was that of Valdemar the Second; and, having directed his deliberate and impartial attention to the subject, he formed a code, distinguished for its wisdom, as well as for its leniency. In 1448, after a reign of seven years over Denmark and Norway, and six years over Sweden, during the whole of which he had proved himself a good sovereign, Christopher died.

Christopher dies, A. D. 1448.

Charles Canutson elected king of Sweden.

Immediately on this event, the Senate of Denmark invited the states of the two other kingdoms to comply with the act of union, by proceeding in concert to the election of a new king. This, however, the Swedes absolutely refused to do, electing Charles Canutson, their own countryman, and the avowed enemy of Denmark, to be their sovereign. The Danes, irritated and surprised at this conduct, assembled a diet at Roschild, and chose Christian of Oldenberg as their sovereign. According to the union of Calmar, a diet, composed of the diets of the three kingdoms, ought to have chosen the sovereign, and drawn up the articles of capitulation for him to sign; but, under the present circumstances, it was found necessary to leave the election to a small number of deputies, most of whom were senators. The Senate, from this period, arrogated to themselves the right of choosing the sovereign, and only occasionally consulted the states, out of form. The articles of capitulation which they drew up for Christian, were very numerous. The following are the most important:—The kingdom of Denmark shall continue to be free and elective: he shall not be authorised to call any foreign prince or noble into the kingdom, nor to assign him any revenue, nor to give him any lands in the kingdom, nor to admit him into the senate, without the consent of the majority of this body: The king shall not be authorised to make peace or war, nor to undertake any important enterprize, nor to give the command of any fortress, but with the consent and approbation of the senate: He shall not mortgage or alienate any lands or fortresses that depend on the crown, except necessity shall oblige him to do it; and then only with the consent of the senate: He shall conform himself to the advice of the senate, with respect to the manner in which he ought to keep his court: He shall not establish any tax without the consent of the senate. From the nature and spirit of these articles, it is abundantly evident that the senate reserved to themselves, in fact, nearly the whole power of the kingdom; indeed, no prince ever before ascended the throne of Denmark with such limited authority. In consequence of the character of Christian for moderation, and the facility with which he had agreed to secure the Danes in their rights and privileges, the Norwegians resolved to elect him their sovereign. For this purpose, the states were assembled at Opsto, and the proposals of Christian being accepted of, he was formally proclaimed king of Norway.

Christian of Oldenberg elected king of Denmark,

and king of Norway.

In the mean time, Charles Canutson, whom the Swedes had called to the throne, created such dissatisfaction among them by his capricious and tyrannical conduct, that a majority of the nation began to repent that they had broken the union of Calmar. Christian, aware of this state of things in Sweden, determined to take advantage of it; and he at length succeeded in compelling Charles Canutson to abdicate the throne, and was himself proclaimed and crowned king at Upsal: thus the three northern kingdoms were again united under one sovereign, agreeably to the union of Calmar. Almost immediately after Christian was chosen king of Sweden, the duke of Sleswick died; this duchy and the country of Holstein had long been held as fiefs of the crown of Denmark; and as the duke died without leaving any heirs, Christian, not only in his character as king of Denmark, but also as near relation of the deceased, had just pretensions to those territories. As Christian, however, before he ascended the throne of Denmark, had bound himself to the late duke, never to unite Sleswick and Holstein to the crown of Denmark, he could not directly and openly put in his claims to them; he adopted more cautious measures: Having assembled the states of these countries, he laid before them his claims, on which, however, he declared he did not mean to insist; but if they chose to elect him, he was willing to secure their privileges to the fullest extent, and in the most solemn and positive manner: he thus succeeded in his object, solemnly declaring in the articles that he signed, that he was elected duke of Sleswick and count of Holstein, *not* as king of Denmark, but by the free will of the states. As soon as he was firmly fixed in the possession of these provinces, he summoned the inhabitants of Hamburgh to pay the homage due to him as count of Holstein; and on their complying with this summons, he confirmed all their privileges.

Canutson abdicates the Swedish throne, and Christian of Denmark elected king.

But Sweden could not remain long quiet and contented; the clergy and the nobles, in particular, were dissatisfied: a rebellion broke out, and the archbishop of Upsal threw off his robes and put himself at the head of a large army. Christian, in this embarrassing predicament, was as much indebted to his character for moderation and good intentions as to his arms; and at last he succeeded in bringing over the archbishop and most of the clergy to his interests. As, however, the nobility still held out against him, and filled the kingdom with dissensions and turbulence, Christian, in a great measure, withdrew his attempts to subdue them, and employed his entire attention in the improvement of his other dominions. A favourite object with him was the establishment of a university at Copenhagen; before that, all the nobility and people of consequence in Denmark were accustomed to send their sons, at a great expence, to be educated at Cologne or Paris; in prosecuting his scheme, however, he met with opposition from a quarter from which he did not anticipate it. The clergy were either indifferent or averse to the establishment of the proposed university; difficulties and delays consequently occurred, and before Christian could complete this and other plans for the benefit and improvement of his kingdom, he died in the year 1481, and in the 55th year of his age. Almost all the contemporary historians concur in representing him as a prince of great moderation, humanity, and liberality; he never permitted his resentment or passion to hurry him beyond the bounds of justice; it was a favourite saying of his, that a king who would be great and reign well, ought to be more compassionate than another man.

Death of Christian. A. D. 1481.

John succeeds his father.

John, the eldest son of Christian, had been received as heir to the crown of Denmark, during the lifetime of his father; and the senate of Norway elected him their sovereign immediately after his father's death. As

History.

the states of Sweden did not seem disposed to proceed to the election of a sovereign, the senate of Denmark, in conjunction with that of Norway, sent deputies to hold a diet at Helmstadt, and invited the Swedes to do the same. At first the Swedes started many objections and difficulties, but ultimately they agreed to acknowledge John as their king, on condition that, to the articles of the union of Calmar, the following should be added: "That three senators of each kingdom should assemble every year to treat of such affairs as should concern the common interest of the three kingdoms; and that this assembly should be held successively one year at Kongsbakke; another at Leedese; and the third at Konselle;" places which, though in the neighbourhood of each other, were situated in the three kingdoms. The states of Holstein and Sleswick objected to continue under the dominion of the king of Denmark, and John was obliged to agree to a compromise, by which his brother Frederic shared with him the authority over these provinces. In 1490, John concluded a treaty of commerce with Henry the Seventh of England, by which their respective subjects obtained full liberty of free traffic with one another, on paying the usual duties on the merchandise which they sold. The English also bound themselves to pay the duties of the Sound, and engaged always to sail through this passage, and not through either of the Belts, except they were forced by a tempest; and in this case, they were to pay at Nyborg, the same duties which they would have paid in the Sound. The English merchants, by this treaty of commerce, were also permitted to have consuls in the principal maritime towns of Denmark and Norway. In 1499, John convoked an assembly of the states of Sweden at Upsal, for the purpose of having his oldest son, Prince Christian, elected his successor. The states agreed to this proposal, and bound themselves, in the most formal and solemn manner, not to elect any other prince after the death of John, but his son Prince Christian. Scarcely was this agreement entered into, before the Swedes were in open rebellion; and having joined the discontented party in Norway, two formidable armies took the field against their sovereign. To oppose these, John sent a large force into Norway, under the command of his son Christian, now 20 years of age: this kingdom was soon reduced to obedience, upon which Christian marched into Sweden, attacked the rebel army, and defeated it. On this occasion, the cruel and vindictive character of this prince first displayed itself; he behaved towards his prisoners in the most barbarous manner, so as to shock his own army, and again drive the Swedes into rebellion. Being convinced that they could now expect no mercy if they were conquered, the Swedes fought with the most determined and persevering bravery; and in order to remove one of the principal causes of their former misfortunes, they elected an administrator to govern the kingdom, who carried on the war against John with various success. Treaties were repeatedly made and broken by the contending parties; the Swedes expressing a wish to submit whenever they were hard pressed, and being again incited to resistance by the administrator, when they had recovered from their difficulties. In these wars with John, they were generally assisted by the people of Lubeck, who excelled in maritime affairs. Towards the end of the year 1510, a desperate engagement took place between the Danish and Lubeck fleets, in which the latter were worsted; the advantage thus gained by John, was, however, in some degree balanced by the success of the Swedes, who in 1511 took Bornholm.

John elected king of Sweden.

Treaty of commerce with England, A. D. 1490.

Rebellion of the Swedes.

In 1512, upon the death of the administrator, Sweden became a prey to domestic convulsions; and the people of Lubeck, tired of the war, took this opportunity to make peace with John. The Swedes, alarmed at this defection of their ally, agreed to appoint a congress, at which peace was concluded, on one of these three conditions, that Sweden should acknowledge John, or his son, for its sovereign; or that it should pay a tribute of 30,000 merks.

A short time before the death of John, which happened in the latter end of the year 1513, he was invited to enter into a league with James IV. of Scotland, and Louis XII. of France, against Henry VIII. of England; this invitation John was prudent enough not to accept; but as he did not wish to irritate the kings of Scotland and France by his refusal, he merely replied, that as James demanded speedy succours, and proposed to attack England immediately, he could not comply with this demand, since his senate, without whose consent he could not come to a resolution of such great consequence, were not with him, and he could not assemble them soon enough for the succours to arrive in good time.

Death of John, A. D. 1513.

The education of Christian II. who succeeded John, had not been such as to qualify him for the throne; he was boarded, during his infancy, with a citizen of Copenhagen, and afterwards with a clergyman of that city; who frequently took him into the great church to sing in the choir, with several young men of very low condition, who were his fellow-boarders. His learning was entirely neglected for several years, till at length he was put under the care of a preceptor from Brandenburgh, who taught him a little Latin. In his temper he was naturally irritable and violent, and this disposition was cherished, instead of being counteracted, by his being permitted to form connections, in his early age, with the most abandoned characters. The king, his father, was for a long time ignorant of his excesses, debauchery, and cruelty; and when he was informed of the manner in which his son conducted himself, his habits were so firmly fixed, that neither admonition nor chastisement produced any effect upon him. With all these faults, however, he was naturally courageous; and upon the rebellion breaking out in Norway and Sweden, he displayed considerable talents for military affairs; but, as has been already mentioned, the victories which he gained by his skill and courage, were rendered almost entirely fruitless by his subsequent tyranny and cruelty.

Christian II. succeeds his father.

Such was the character of Christian II. when he ascended the throne; no good was anticipated from it, and he soon gave unequivocal proof that his public conduct would be unprincipled and ferocious: his chief counsellors were his mistress and his drunken companions, people of the lowest rank, and of the most profligate manners. The states of Denmark were so apprehensive and alarmed, that they offered the crown to Frederic, duke of Holstein, the brother of the late king; but the offer was, at this time, not accepted; and the states, afraid of the vindictive spirit of Christian, kept it a profound secret, and acknowledged him king of Denmark and Norway, after he had bound himself to confirm the liberties and privileges of the two countries. At the assembly which was convoked on this occasion, deputies from Sweden were present; but they had not power to choose Christian king of Sweden; and by their representations on their return to their own country, induced the states of Sweden to declare openly against this prince, and to

Sweden declares against Christian.

History.

elect an administrator to hold the reigns of government. Christian, at first, did not attempt to reduce the Swedes, but contented himself with augmenting his power in Denmark; in effecting this, he was, however, opposed by the clergy and nobility, whom his natural disposition led him rather to oppose and oppress, than to conciliate; so that at the very time that he was at war with the Hanseatic towns, he found the great majority of his clergy and nobles at variance with him, and only waiting for a favourable opportunity to break out into open rebellion. Thus deprived, in a great measure, of the good will and support of his subjects, he resolved to strengthen and protect himself by other methods; and, with this intention and hope, he married the sister of the Emperor Charles V. He also perceived that commerce had introduced into Denmark a new order of men, whom, by encouraging their trade, and promoting their interests, he might possibly unite to himself in his opposition to the nobles and clergy; he accordingly gave many privileges to the merchants, and freed them from many vexatious impositions. Before his time, they were obliged to send all their merchandize to the Hanse Towns, at a very great expense, and to permit the magistrates of those towns, who were for the most part merchants, and therefore interested persons, to put a price upon their goods; the obvious and natural consequence was, that the Danish merchants were frequently obliged to sell their goods to a great disadvantage. In order to prevent these vexations, Christian issued orders that all the Danish merchants should send their goods to Copenhagen; and as they might be under apprehensions of his rapacity, he placed in the hands of the magistrates a very large sum of money. To induce foreign merchants to settle in Copenhagen, he granted them particular protection, and the most extensive privileges. While he acted with this wise policy towards all engaged in trade, towards the clergy, nobles, and the mass of the people, his conduct was tyrannical and oppressive: the revenue which an increased commerce gave him was principally expended in supporting a large number of regular troops; thus imitating the other sovereigns of Europe, who, about this time, first began to keep a standing army. With the assistance of these troops, he began to exercise his power with the greatest rigour, and to meditate the accomplishment of essential changes in the constitution, by the most violent and arbitrary means. At first the clergy and nobility were silent and inactive, through surprise and astonishment; and the king, thinking that they were intimidated, proceeded in his plans with still greater rapidity and boldness. Without the consent of the senate, and in direct opposition to the capitulations that had been signed by his predecessors and himself, he laid on new and oppressive taxes; and in order to strike terror, and silence the murmurs of the people, he ordered a gallows to be erected in the most public place in every town. In short, every action which he performed had for its object the breaking down the power of the clergy and nobles, and tyrannizing over the people: he still retained his mistress, and his profligate favourites, whom he consulted in all his schemes, to the utter neglect of the senate. Christian had been particularly blamed for his conduct to the nobility and clergy; but had he been moderate and just to the people at large, his conduct to these classes might have been excused; indeed it was almost called for by the circumstances of the times. The greatest part of the lands had fallen into the possession of the nobles, who were thus enabled to oppress the common people; while they had nearly in an equal degree touched on the prerogatives of the crown. Christian, therefore, seems to have had no alternative; he must either have submitted to have been the slave of his nobles, or have acted as he did, and reduced their power; he is, however, blameable, in that his measures were so oppressive and violent, and that his object was not to benefit the people, but himself.

His regulation in favour of commerce.

He perhaps would have found more difficulty in curbing the pride and reducing the power of the clergy, had not the doctrines of Luther begun to extend themselves about this time: of these Christian availed himself; and had he managed the opportunity with less violence, and with more caution and prudence, he might have completely annihilated the powers and privileges of the clergy; but the natural impetuosity of his disposition prevailed, and he incensed without materially humbling them. In the mean time, the affairs of Sweden were in the utmost confusion; the administrator, who had been just elected, was opposed by the clergy, with the archbishop of Upsal at their head, who formed a party to elect Christian king of Sweden. On the receipt of this unexpected and welcome intelligence, the king marched a body of troops to Schonen, under the command of Crumpen, an officer of great merit and experience. Although it was the depth of winter, such was the impatience of Christian, that he ordered Crumpen to enter West Gothland, and to endeavour to bring the enemy to battle. The administrator had not been idle; but having collected a numerous army, he marched to meet the Danes. Three battles were fought; the first decided nothing, in the second the administrator was wounded, and in the third the Swedes were completely defeated, the administrator dying soon after of his wounds. This success enabled Crumpen to march into the heart of the kingdom; and in the beginning of the following year, (1520) Christian, having arrived in Sweden, and Stockholm being reduced, he was formally proclaimed king. During his absence from Denmark, the discontented there flattered themselves with the hopes, that they should be able to organize such a force, as would enable them successfully to oppose him; but when he returned the conqueror of Sweden, they became silent and submissive.

Christian subdues Sweden, and is proclaimed king, A. D. 1520.

Christian soon discovered to the Swedes, that he meant to treat them as subjects of a conquered country. It had always been customary at the coronation of their kings, for the new monarch to make a certain number of knights; Christian complied with this custom in so far as to create the usual number, but they were all Danes and other foreigners; not a single Swede did he advance to that honour; and lest his motives might not be misunderstood, he publicly declared, that henceforward he would not shew any mark of honour to a Swede, "because he owed that crown to his arms and not to their free-will." This was only the beginning of his arbitrary and tyrannical conduct to this nation. Being embarrassed in his finances, and despairing of raising money with the consent of the senate, he formed a plan to massacre all the members of it. This plan is said to have been suggested to him by his mistress; it was communicated to the archbishop of Upsal, and received his sanction. The senate and the states of Sweden were accused of heresy, and were taken into custody on this accusation; but even the forms and delay of a mock trial were too slow for Christian's vindictive temper. He ordered the victims to be marched out in the middle of the day, surrounded by soldiers. Among the first was Eric Vasa, father of the

His cruelty to the Swedes.

History.

celebrated Gustavus Vasa. At the place of execution, 70 senators, lords, and bishops were executed; even then the cruelty of Christian was not glutted with blood. Being informed that several of those whom he had marked out could not be found, he ordered the soldiers to massacre all the people of rank whom they met in the streets, and to search the houses for them. A similar massacre took place in the provinces on all who were obnoxious to Christian, or had espoused the party of the administrator.

The Swedes under Gustavus attempt to recover their independeace, A. D. 1522.

But the day of retribution was at hand. Gustavus, son of Eric Vasa, roused the peasantry of the Swedish provinces, especially those of Dalecarlia, to attempt the restoration of their country's liberty and independence. In vain did Theodore the king's viceroy oppose Gustavus; he was compelled to return to Stockholm, which city, in the year 1522, was invested by the Swedish hero. To raise the siege, Christian sent a powerful fleet and army under Norby, who at first gained some advantages over the Dalecarlians, but was soon afterwards compelled to reimbark, having thrown supplies of men, stores, and provisions into the city. Gustavus, however, made little real progress in reducing it for want of a fleet. He therefore entered into a treaty with the inhabitants of Lubeck, who supplied him with a squadron. Stockholm was now reduced to such extremity, that Norby resolved to make another attempt to relieve it; he accordingly appeared before it with a large fleet, and attacked the auxiliary squadron of Gustavus. A storm put an end to the contest, and Norby taking shelter in a creek, his fleet was there fixed by a sudden frost, and thus exposed to the attacks of the enemy. In this situation, Gustavus resolved to attempt its destruction, but meeting with a formidable resistance, the Lubeckers retreated in the very middle of the battle. The ice was soon after dissolved, and Norby took advantage of this favourable circumstance to effect his escape.

Revolt in Denmark.

Denmark, in the mean time, was a scene of the utmost confusion, and the province of Jutland was in a state of open revolt. A general diet was held at Wyburg, by which Christian was formally deposed, and a particular decree passed, stating the reasons for this proceeding. As soon as the king was informed of his deposition, he set out for Kolding, a town situated on the frontiers of Holstein and Jutland. Copenhagen, the islands of the Baltic, and Norway, were still in his power; but as he was conscious that he held them by a frail and uncertain tenure, and that from them he could not expect to draw the means of quashing the rebellion in the other parts of his dominions, he formed the resolution of abdicating the throne. Before he put this resolution into practice, however, he went to Ringstadt, where there happened to be a great fair; here he harangued the populace with such effect, that they took a fresh oath of allegiance, and offered to assist him against all his enemies; but he was now grown distrustful, and being apprehensive that if he delayed any longer, he should not be able to escape from Denmark, he resolved on immediate flight, and retired with his family into the Low Countries.

Christian abdicates the throne,

And retires to the Low Countries.

Character of Christian.

The character of this prince has been already sketched, and indeed it is sufficiently apparent from the whole tenor of his political life; yet cruel and tyrannical as it undoubtedly was, many of his measures displayed considerable wisdom and a sense of justice. In the year 1521 he published a code of laws, which greatly limited the power of the nobility over their vassals, and retrenched several branches of their revenues. By this code they were expressly forbidden to sell their vassals as slaves. The article which relates to this traffic exhibits a dreadful picture of the state of the peasantry at that time: "The wicked and impious practice, which is followed in Zealand, Falster, Laaland, and other parts of Denmark, of selling the poor farmers, and of making a traffic of Christians, shall be abolished for ever; and when the proprietors of lands shall use their vassals with injustice, the latter shall be permitted to leave the lands of the former, and to settle themselves in other lands, as is the custom among the farmers in Scania, Jutland, and Funen." In the same year he published a code of ecclesiastical laws, in which it is declared that a bishop shall not have more than 14 persons in his train when he is on a journey, and an archbishop not more than 20. Before the passing of this law, these prelates were generally accompanied with 100 knights and other attendants, who treated the common people with great indignity, cruelty, and oppression. Another law which he passed shall be noticed, because it not only throws great light on the customs and the state of society of Denmark at this æra, but also exhibits the character of Christian to great advantage. By this law, the practice of robbing and plundering ships which had been wrecked, was forbidden. It was expressly ordered, that all the king's officers should assist the seamen to the utmost of their power, in saving the ships and cargo; if they refused, they were liable to be hanged, and to have their goods confiscated; if all the seamen were drowned, the countrymen were obliged to keep the effects saved from the wreck, for a year and a day; and if within that period the owner claimed them, they were to be given up to him upon his paying salvage; if they were not claimed within a year and a day, they were to be divided, and two thirds were to be the property of the king, and the other third the property of the curate of the parish. Even the wages of those who might be employed in saving the effects was fixed by law; and if the owner of the ship was forced to sell any part of the cargo in order to pay these men, the king's officer was obliged to render to him faithfully all the money that might arise from such sales; if he did him injustice, he was liable to suffer death.

History.

Wisdom of his enactments.

This law was particularly disagreeable to the Danes, especially the nobility and clergy. Before it was passed, many of them made a considerable revenue by plundering ship-wrecked vessels. The bishops of Borghum in Jutland frequently employed 300 men on the sea coasts, when there was any appearance of a tempest which might drive ships ashore, in order to compel the seamen to suffer their goods to be plundered without making any resistance, or if they made resistance, to massacre them. "Herman Grice, one of the senators, having represented to the king the wrong which he did himself by this law, as he would lose thereby a considerable revenue from Jutland alone, besides what he would lose in the other provinces, Christian returned him the following answer: "I would rather lose all the revenues of which you speak, than suffer those unhappy people to be so unjustly treated." One of the bishops likewise complained to the king of the wrong which he had done him in particular by this law, and demanded permission to follow the ancient customs of the country with regard to this matter; to which Christian answered, that his intention was not to make any change in those customs, except in such as he found to be contrary to the divine laws; whereupon this conscientious prelate replied, by ask-

History.

ing, "How the ancient customs of the kingdom, respecting shipwrecks, were contrary to the divine laws?" To which the king again replied, "Thou shalt not kill, thou shalt not steal."

Frederic Duke of Holstein proclaimed king of Denmark.

As soon as the flight of Christian was known to Frederic Duke of Holstein, his uncle, he entered Jutland, where he was proclaimed king: the capitulation which the clergy and nobility obliged him to sign, limited and controuled his power exceedingly, while it extended their privileges and rights. By all the former capitulations, which the Danish sovereigns had signed, these orders of men had never been able to obtain a legal sanction to the right which they claimed over the lives of their farmers; all they could obtain was the right of judging them for small offences; but by one of the articles of the capitulation, which Frederic signed, the nobles obtained, formally, not only the right of life and death over their farmers, but also that of condemning them to lose all their goods, whenever they supposed that they had acted illegally: this power the king could not in reality bestow, since by the fundamental laws of the constitution of Denmark, the farmers formed a distinct order of the state, and had always been recognised, though not always treated as such. The oppression and tyranny to which this extended right of the nobility gave rise, was so galling and insupportable, that the people began to entertain those feelings and sentiments which afterwards made them concur in that revolution, which entirely changed the constitution of Denmark. In a letter written about this time by a Danish ecclesiastic to his friend, published by Pontoppidan, it is expressly stated, that "the people in general are of opinion, that they had better suffer patiently the tyranny of one person, than have so many tyrants at a time, whose insatiable avarice and pride are not to be borne." With respect to the clergy in particular, they obliged Frederic to burn that law of Christian the Second, which prevented the robbing of vessels that were shipwrecked, as contrary to the laudable customs of the country. As soon as Frederic felt himself secure in the throne, he turned his thoughts against Sweden; at first he entertained hopes that he should be able to deprive Gustavus of that kingdom; and for that purpose he sent ambassadors to the Swedish senate, complaining of the election of that monarch, in prejudice to his superior right, and in direct violation of the union of Calmar. But the Swedish nation were too well satisfied with Gustavus, to feel any inclination to dethrone him, and too conscious of their own power to be apprehensive of the designs of Frederic. When the Danish ambassadors opened their business before the diet, the members of it not only refused to give them any countenance, but they openly declared before them, that they would extend the privileges of Gustavus beyond what any former monarch had possessed, by granting the power to declare peace and war. Gustavus, on his part, treated the ambassadors with great attention and respect; but in order to impress upon their minds the state of preparation for war in which he had placed Sweden, he reviewed the troops before them, and carried them to inspect the arsenals, &c. In consequence of the report of the ambassadors, and of the behaviour of a skilful agent whom Gustavus sent to the court of Copenhagen, an alliance was formed between the two monarchs. But shortly afterwards, a cause of difference arose between them: Norby, who commanded the Danish fleet, refused to acknowledge Frederic, commenced pirate, and committed great ravages on the shipping of Lubeck and the other Hanse Towns: they complained to Gustavus, who resolved to chastise Norby, and at the same time attempt to gain possession of the isle of Gothland, in which the admiral had taken shelter, and which had formerly belonged to Sweden. Norby now expressed his willingness to submit to Frederic, provided he would protect him from the Swedes: the admiral was accordingly relieved; but disputes arose between the two monarchs respecting Gothland; and the Swedish monarch besieged Wesby, the principal town in the island. Frederic, however, having thrown considerable supplies into it, Gustavus, convinced he could not reduce it, raised the siege.

The wise enactments of Christian repealed.

Alliance between Gustavus and Frederic.

In 1526, an attempt was made to reinstate Christian by Margaret of Austria: for this purpose she sent some ships into the Baltic, but nothing was effected. Frederic's attention at this time was principally occupied by the religious disputes which arose in his kingdom: he himself had embraced the Protestant religion, but the nation was divided into two parties, filled with the most bitter rancour against each other. The policy of Frederic on this occasion was liberal and enlightened: he published an edict, prohibiting all his subjects, under very severe penalties, from laying any restraints on conscience, or in any manner depriving a man of his fortune, reputation, or liberty, on account of his religious opinions; the doctrines of the reformed religion were also permitted to be preached openly, without the least molestation. This edict was soon afterwards ratified at a general diet of the states, at which it was also decreed that the religious of all orders should be permitted to marry, and live in any part of the kingdom they thought proper, without respect to particular monasteries, &c. In consequence of this decree, the abbeys and cloisters were deserted: Lutheranism now spread rapidly; the city of Malmo publicly prohibited mass, and the other superstitions of the Romish church; and its example was soon followed by the other cities and towns: the New Testament was also translated into the Danish language.

Religious disputes.

Universal toleration established by law.

The progress of the reformed religion, and the countenance and support which Frederic gave to it, rendered him very obnoxious to the clergy; and Christian, informed of the state of Denmark, resolved to make another attempt to regain the throne. He was enabled, by the assistance of the emperor, his brother-in-law, to raise a considerable force in the Netherlands, with which he invaded Norway: at first he gained a footing there, and was joined by all the malcontents, especially by those who still adhered to the Roman Catholic religion. Frederic was alarmed, and sought the assistance of Gustavus and of the Landgrave of Hesse, both of whom, principally because they considered the cause of the reformed religion might be injured by the success of Christian, sent him powerful reinforcements. At the same time, Frederic equipped a fleet, which came up with Christian's fleet before Babus: here they attacked them: the engagement continued the whole day, when it ended in the total destruction of the fleet, which had brought Christian from the Low Countries to Norway. Thus cut off from all chance of escape by sea, this unfortunate prince endeavoured to penetrate into Sweden; but in this attempt he was opposed by a body of 3000 Swedish horse. He was soon afterwards compelled to surrender, the Danish generals engaging themselves to grant him a safe passport into the Netherlands; but this engagement was most shamefully broken; Christian was carried to Soldenberg, in the isle of Alsen, where he was shut up in a dungeon, with only a dwarf

Christian attempts to recover the throne.

Is defeated,

And surrenders.

History.

to keep him company; the door of the dungeon was immediately walled up, only one small window being left, which served both to give light to the place, and to convey provisions to the prisoner. Here he continued till the death of Frederic, which happened at Gottorp in the year 1533.

Frederic dies, A. D. 1533.

Frederic left two sons, Christian and John: the latter had been brought up in the Catholic religion; the former was a Protestant. The bishops, who had repented of their opposition to Christian the Second, when they perceived that Frederic favoured the reformed religion, were desirous that John should succeed his father. As soon as Frederic's death was known, the senate convoked the deputies of the different orders of the states at Copenhagen. The bishops opened the debate, by inveighing, with great zeal and warmth, on the subject of religion; and when they found that the lay senators did not coincide with their opinions, they demanded that the decree of the diet of Odensee, which had given the nobles such extensive power over their farmers, should be annulled: the nobility were alarmed, and endeavoured to sooth the clergy, but the latter feeling their weight in the assembly, carried their point so far, that the tenths were restored to them. The next subject discussed related to the choice of a successor to Frederic; the Catholic and ecclesiastic senators declared for John; the lay and Protestant senators for Christian; debates ran high, till at last it was proposed that the states of Norway should be invited to send their deputies. Although these were all Roman Catholics, yet the proposition was so fair, that the Protestant senators could not object to it. The bishops considering the election of John as now secure, began to persecute the reformists, and to harass the people with heavy taxes. The friends of Christian the Second, considering this a favourable opportunity to endeavour to reinstate him, made an attempt to that effect; but this attempt, though at first successful, ended in the election of Christian the Third: for the bishops, alarmed at the endeavours to reinstate Christian the Second, and perceiving that their former conduct had incurred the indignation of the nation at large, consented to the election of Christian the Third, on the condition that the privileges and rights of the senate and states should be confirmed, and that he should not be the enemy of their religion. The rights of all classes, except those of the farmers, were amply secured by the capitulation which Christian signed, when he ascended the throne; but the farmers were, if possible, in a still worse and more oppressed condition than they had ever been before.

Disputes respecting the succession.

Christian III. elected king.

Christian found the state of public affairs such as required the display and exercise of considerable energy and activity, united to moderation and forbearance: the differences on religious subjects still existed; the army that had been sent to reinstate Christian the Second, was still in possession of some part of the Danish dominions, and had been joined by all the discontented. The province of Fioni demanded his first and principal attention: the Count of Oldenberg, who was at the head of the invading army, had reduced nearly the whole of it, and though it was restored by a victory which Christian gained over this general, yet no sooner did the king leave it to prosecute the war in other parts, than the Count returned, and being assisted by the whole body of farmers, again subdued the whole province, and made them take a new oath of fidelity to Christian the Second. In this situation of affairs, Christian the Third had recourse to the King of Sweden, who coming himself at the head of a large force, turned the fortune of war in favour of his ally. The troops of the Count of Oldenberg were soon driven out of Jutland, and afterwards out of Fioni, by Christian's army; while Gustavus reconquered Scania. The Count was now obliged to act on the defensive, and to retire into Zealand, where he shut himself up in Copenhagen. The siege of this place was immediately undertaken: it made a long and obstinate defence, but at last it was reduced, and the Count of Oldenberg was taken prisoner.

State of religion.

As soon as Christian the Third was firmly seated on the throne, he turned his attention to the state of religion; and resolved to carry into execution a plan which had been communicated to him by Gustavus, for reducing the power of the clergy. He accordingly assembled the senate with great secrecy, and they immediately came to the resolution to annex all the church-lands, towns, fortresses, and villages, to the crown, and to abolish for ever the temporal power of the clergy. All the bishops in the different parts of the kingdom were arrested about the same time; and that the nation might not be alarmed by this extraordinary measure, the king convoked the states at Copenhagen; the nobility were ordered to be there in person, and the commons by their deputies, but the clergy were not summoned to attend. After a strong speech from the king against the rapacity of the clergy, the senate confirmed the decree of the diet, and the power and privileges of the clergy were declared to be annihilated for ever. The senate next settled the succession in the person of Duke Frederic, the king's eldest son. In return for these concessions, the king confirmed the nobility in all their rights, particularly in what they called the right of life and death over their vassals, and of punishing them in what manner they thought proper. Thus was the power of the clergy for ever destroyed in Denmark; but the conclusion which the nobles drew from this, that their own authority and power would be so much the more augmented, was soon proved to be erroneous; for as a great part of the crown-lands had fallen into the hands of the clergy, these lands being again annexed to the crown, the royal authority was considerably increased. The oppression of the farmers still continued, and the nobles displayed a restless and increasing desire to prevent them from ever rising in the state; for the senate passed a law, forbidding any person, either ecclesiastic or secular, who was not noble, to buy any freehold lands in the kingdom, or to endeavour to acquire such lands by any other title.

Disturbances in Norway, A. D. 1536.

Norway was still unwilling to acknowledge Christian; the Catholic religion kept its ground there longer and more firmly than it did in Denmark. The states of the former kingdom being assembled at Drontheim, in the begining of the year 1536, Christian sent notice to them that he was king of Denmark, and demanded, by virtue of the union of the two kingdoms, to be elected their king also; but the clergy representing this demand as haughty, and the presage of a tyrannical government, the people rose in a tumultuous manner, massacred several of the king's friends, and compelled the rest to quit the kingdom. Christian on this resolved to have recourse to the most decisive measures. He accordingly marched an army into Norway, and before the end of the year, the whole kingdom was reduced to a state of obedience and tranquillity. The Danish nobility persuaded the king to take advantage of the subjugation of Norway, to strip this kingdom of its independence; and a decree was accordingly passed, stating, that as the kingdom of Norway had declined in

History.

Norway annexed to the crown of Denmark.

its power and resources, so as to be no longer capable of supporting a king; and as the greatest part of its senators had shewn themselves enemies to the crown of Denmark; therefore the said kingdom of Norway shall be, and for ever remain subjected to the crown of Denmark; so that in future it shall no more be a kingdom a part, nor shall it any more be so called, but shall be a part of the kingdom of Denmark. It was, however, stipulated, that in case Norway should be engaged in war, the senate and the estates of Denmark should assist them. This decree was carried into immediate and full execution. The senate of Norway was suppressed, the states no longer had any influence in the elections, and the Danish nobility were appointed to most of the places of confidence and emolument in that kingdom.

Christian III dies, A. D. 1558.

In 1546, Christian the Second publicly and formally renounced all his claims to the crown of Denmark, binding himself never to go out of the fortress of Cattenberg but with the king's consent, and to hold no communication with strangers. Nothing else remarkable occurred during the reign of Christian the Third, who died on the 1st of January 1558.

Frederic II. elected king.

He was succeeded by his son Frederic the Second, who greatly resembled him in disposition and character. His first warlike enterprize was against that part of the Duchy of Holstein, called Ditmarsh, the inhabitants of which refused obedience to the kings of Denmark, or the Dukes of Holstein. In his war against these people, he was joined by Count Rantzaw and Duke Adolphus, who, from the vicinity of their territories to Ditmarsh, were interested in the quarrel. The confederates first attacked and carried by assault the city of Meldorp; they next proceeded to Heida, where the Dithmarsian army suffered a total defeat. Peace was soon afterwards granted to this people, on condition that they should do homage to the kings of Denmark and Dukes of Holstein; that the forts erected by the Dithmarsians should be destroyed, and that the confederate princes should have liberty to build three forts in any part of the country they chose. In 1563, in consequence of some trifling disputes between Frederic, and Eric who sat on the throne of Sweden, hostilities commenced between the two countries. Frederic on this occasion formed an alliance with the inhabitants of Lubeck, who had long been at variance with Sweden, on account of the restrictions which that government had imposed on their trade. After a maritime engagement, in which the Danes were the aggressors before any formal declaration of war, and in which they were worsted, Eric, either naturally of a pacific disposition, or alarmed at the great preparations of his opponent, made offers of peace. These were refused by Frederic, who had now an army of 80,000 infantry, a large body of horse, and a strong fleet, besides the squadron of his allies, the Lubeckers. The whole operations of the first campaign, in 1563, consisted in the reduction of Elfsburgh by the Danes. During the winter, the Elector of Saxony and the Prince of Hesse endeavoured to negociate a peace, but the offer was now declined by Eric. As soon as the spring permitted it, the hostile fleets put to sea; an engagement took place, and the Swedes were totally defeated: nor was Eric more successful in his invasion of Norway, from which kingdom his army was obliged to flee with a disgraceful and ruinous rapidity. He was not, however, dispirited; and having collected a large fleet, a desperate engagement took place between Wismar and Rostock; it lasted for three days; both sides fought with great obstinacy and skill; on the third day the Danish admiral was taken; this decided the batle; and for the remainder of the year the Swedes remained masters at sea. The war also raged by land. Eric commanded his army in person; and after several partial engagements, a decisive battle took place near Wardeburgh. The Danish army was commanded by Count Rantzaw; it was much inferior in number to the Swedes. Eric trusting too much to this circumstance, quitted an advantageous post, attacked the Danes in a narrow defile, where his numbers could be of little advantage, and was defeated with the loss of 7000 men, and all his artillery. The Danes, however, gained little by this victory but glory; and the war continued with increased rancour, and with various success. Eric, towards the end of 1566, was persuaded to invade Norway, by the representations of a person who called himself a Norwegian noble, and who persuaded the king that his countrymen were ripe for revolt. Eric soon found that he had been deceived, and he was compelled to retire from Norway, after suffering a severe defeat. In 1568, a civil war broke out in Sweden; and the malcontents concluded a peace with Denmark, on terms very injurious to their own country. The war was renewed, and carried on with great bitterness, but with little success on either side, in 1569, till the end of the following year, when a more equitable and permanent peace was concluded. The Danish monarchs having gradually increased the duties of the Sound, and having frequently exacted them with unnecessary strictness and rigour, the English, Dutch, Lubeckers, and Hanse Towns, remonstrated against them entirely, in the year 1583; but their remonstrances were in vain, and they were under the necessity of submitting to the mode and extent of these exactions. Towards the conclusion of Frederic's reign, Denmark began to rise in importance among the European powers. An embassy came from Elizabeth, Queen of England, with the order of the garter for the Danish sovereign; and in 1588 a treaty of marriage was proposed between a Princess of Denmark and James the Sixth, King of Scotland. Soon after this, Frederic died, in the 54th year of his age, and in the 29th of his reign.

Regency during the minority of Christian IV.

Christian the Fourth was only eleven years old when his father died; a regency was therefore appointed, who performed their duty both to the young prince and to the kingdom in the most exemplary manner. Every measure was taken which could ensure the proper education of Christian, and the tranquillity and prosperity of the people. As soon as this prince assumed the royal power, he directed his thoughts and his preparations to a war with Sweden; the pretexts that he urged for commencing this war, were rather frivolous. Charles the Fourth, who then sat on the throne of Sweden, had assumed the title of King of Lapland; this gave great offence to his Danish majesty, who regarded Lapland as a dependence on Norway; and in his declaration of war, this grievance was strongly held forth. Hostilities commenced, on the part of Christian, by the siege of Calmar in 1611. The city was soon taken, but Charles, with an army of 16,000 men, defeated the Danish general in the absence of the king, and obliged him to raise the siege of the citadel. As soon, however, as Christian returned, the siege was renewed, and the citadel surrendered. Bornholm and Oeland also yielded to the Danes; and Charles, irritated at these disgraceful disasters, challenged Christian to single combat; the challenge was contemptuously refused; and this circumstance is supposed to have occasioned, or hastened the death of the Swedish monarch. He was

History.

succeeded by the famous Gustavus Adolphus, who turned the fortune of the war; and in 1613, a peace was concluded by the mediation of the King of England. From 1614 to 1623, Denmark was at peace; and Christian turned his whole attention to the encouragement of trade and commerce. In 1621, a treaty of alliance was concluded between the Kings of England, Denmark, and Sweden, several of the princes of the empire, and Holland. The object of this treaty was to support the Elector Palatine, in whose favour, in 1623, Christian took up arms, and was appointed head of the league, and commander of the forces of Lower Saxony. He was, however, not equal in military talents or experience to the Imperial general, Count Tilly, by whom he was completely defeated near Rottenburgh, in 1626. His infantry being entirely cut to pieces, he was compelled to retreat with his cavalry, continually harassed by the enemy, who followed him into Holstein. In a very short time the whole of this province fell into their hands; and when Christian attempted to prevent their entrance into Jutland, he was deserted by his troops. The people now suffered severely under the exactions and ravages of the Imperial troops, while the senate in vain endeavoured to bring about a peace. Christian, convinced that he ought to prepare for the worst, renewed his alliance with England, Sweden, and Holland; and having fitted out a fleet, he recovered part of his dominions. Both sides were now tired of the war, and peace was concluded on condition that his Imperial majesty should not interfere in the affairs of Denmark; that all the places taken from Denmark should be restored; and that his Danish majesty should cede to the Houses of Sleswick and Gottorp all the territory which belonged to them by hereditary right. In 1630, a dispute arose with the city of Hamburgh, in consequence of Christian bestowing on Gluckstadt several important privileges, and imposing duties on all vessels that sailed up the Elbe. The dispute was carried on with great acrimony; and notwithstanding the endeavours of Lubeck and Bremen to reconcile the parties, hostilities commenced. Christian assembled a large fleet at the mouth of the Elbe, and was preparing to attack Hamburgh, when he thought proper to desist from his enterprise, in consequence of his apprehension or jealousy of the king of Sweden. The Imperial court, which at this period was greatly alarmed at the brilliant conquests of Gustavus in Germany, were very anxious to foment the differences between him and Christian; Pappenheim, the Imperial general, succeeded in irritating Christian against the king of Sweden; but the Danish senate suspecting his design, prevented a rupture between the two countries. In 1632, Christian offered his mediation to restore peace to Germany; but as he was suspected of favouring the court of Vienna, Gustavus declined the mediation. In 1637, the world was astonished by a chimerical enterprise of the Danish king, at once to ruin the commerce of Holland, and to conquer Sweden. In this most rash and absurd undertaking, he was to be joined by Spain and the duke of Holstein; and the former actually embarked a great number of troops; but the whole scheme was defeated by the victory that Tromp, the Dutch admiral, gained over the Spanish fleet in the British Channel. At the moment, Sweden concealed her indignation at this scheme of Christian's; but no sooner had she begun to negociate a peace with his Imperial majesty, than general Torttenson entered Denmark with a powerful army, and advanced as far as Jutland without resistance: in this province he was opposed, but with such inadequate means, that he soon conquered nearly the whole of it. Hitherto Sweden had assigned no reason for this sudden commencement of hostilities; but as all Europe was astonished and indignant at her conduct, she issued a manifesto, in which she exposed the clandestine treaty, which Denmark had formed with Spain and Holstein. The Swedes still continued to advance, and count Horn, who now commanded them, prepared to invade Funen and Zealand; but Christian, recovered from his surprise, had put the fortresses into such a good state of defence, that the Swedish general was obliged to desist from his enterprise. Christian, perceiving that the enemy, though prevented from advancing and extending their conquests, still retained those which they had made, resolved to march himself at the head of a powerful army into Sweden. He accordingly crossed the Sound, and laid siege to Gottenburgh, while a large fleet blockaded it by sea. Horn upon this evacuated Denmark, and marched to raise the siege; this he probably would not have been able to effect, had he not been assisted by the Dutch, who sent a fleet for this purpose. Christian soon afterwards solicited the mediation or the assistance of his Imperial majesty, who, after some delay, took effectual measures for the protection of Denmark. France, about the same period, offered her mediation, which was accepted; but before the terms were adjusted, the Danish fleet suffered a most severe defeat off the isle of Femren. The Danish admiral, vice admiral, and 12 ships of war, were taken, and 4000 men killed; several more ships were run on shore; so that of the whole fleet, only two got safe into port. At length, in 1645, peace was concluded, by which Sweden obtained the islands of Gothland and Oesel, the provinces of Jenetland, and Harndalen, which had belonged to Norway, and the possession of Halland for 30 years: this last was given as a full security of the right of navigation and commerce in the Sound and Great Belt; on the other hand, Sweden restored to Denmark all the cities, &c. which had been conquered during the war. From the conclusion of this peace till the death of Christian, nothing memorable occurred. He died in the month of February 1648, at the age of 71, and in the 60th year of his reign.

"Christian was possessed of admirable qualities of mind and body, but had a vindictive obstinacy of temper, which made him pursue his animosities beyond the dictates of prudence. To his last day he retained all the fire and vehemence of youth; commanded his fleets and armies in person, after he had worn the crown nearly sixty years; threw himself in the midst of dangers, at an age when the faculties of the mind and body are usually enervated; was to the last jealous and tenacious of the dignity of the crown, and the happiness of his people; though too strict a regard for the former proved all his life the destruction of the latter. On the whole, however, he was a monarch of an able head, strong arm, extensive capacity, and great magnanimity, qualities unhappily tinctured with violent passions, which frequently obscured every ray of understanding, and locked up the exertion of that solid reason with which nature had endowed him." His memory is still held in great esteem and reverence by the Danes. In his reign, the Danish settlements in the East Indies, and the Danish joint companies trading to Greenland and Iceland, were established.

Christian left many children, but only one that was legitimate, a son named Frederic; he of course had a right to the throne: but many of the Danish nobility

His character.

History.

were disposed to elect Valdemar, one of his natural sons, in the expectation that if he were king, he would be disposed, in return for the dignity to which they had raised him, to extend their privileges. It has been already seen, that the privileges of the nobles were enlarged by almost every monarch; and the power and presumption with which they were thus invested, were much increased, by the circumstance, that almost all Christian's illegitimate daughters were married to Danish noblemen. Frederic, alarmed at their disposition to prefer Valdemar, agreed to accept the throne upon any conditions that they would prescribe. They accordingly insisted, that they should be freed from the payment of the usual contributions towards the support of government; that all posts of honour and profit should be exclusively bestowed upon them; and that the commons should be excluded from all military preferment above the rank of captain. Articles to this effect were inserted in the capitulation which Frederic signed; and this monarch thus ascended the throne, a greater slave to his nobility than any of his predecessors. The state of Denmark at this period required a monarch of great talents; firmness, economy, and moderation, were absolutely requisite; the army of Denmark had been nearly annihilated by the wars in the last reign; her marine was in a condition little better than the army; there was scarcely any money in the treasury; the nobles were exempted from the payment of taxes; and the people were so poor, or so discontented, that to levy the necessary taxes on them would have been impracticable, and the attempt excessively dangerous. The states of Norway seemed disposed to throw off their dependence on Denmark, and assume a republican form of government; and Sweden was evidently preparing to take advantage of the reduced and humble condition of her rival. The first object of Frederic was to arrange with the Dutch respecting the payment of the Sound duties. Frequent disputes had arisen with this commercial people on that subject; and the maritime assistance which, during the preceding reign, they had afforded to Sweden, may be traced, in some measure, to the circumstance of the Danes having increased these dues. A treaty was therefore formed between Denmark and Holland, consisting of two parts: By one part, called the redemption treaty, the Dutch agreed to pay 150,000 florins yearly, for the free passage of the Sound. This treaty was objected to by the Danish ministry and merchants, and even by the Dutch merchants themselves. The ministry contended, that the revenue, which might fairly have been drawn from the dues levied on the Dutch ships which passed the Sound yearly, would have been double the redemption sum. The merchants were apprehensive, that if the public revenues were not sufficient, and the government should be under the necessity of laying on other taxes, these taxes would fall upon them; and the Dutch merchants complained, that their interests had not been sufficiently attended to. The other part of the treaty was one of alliance, by which each power bound itself to furnish the other with 4000 men, in case it was attacked. This last treaty Frederic was soon called upon to fulfil. In 1652, the Dutch envoy at Copenhagen called for the stipulated forces, in consequence of an approaching war between Holland and England; but the Danish monarch hesitated to comply, as he contended that the Danish envoy had not proved that England had been the aggressor. He was also apprehensive, that if he assisted Holland, Sweden would unite herself with England.

Frederic elected king.

Treaty with the Dutch.

A. D. 1652.

The Dutch were extremely anxious to gain the assistance of Frederic, who resolved to take advantage of their anxiety to gain a large subsidy from them. In the mean time, to convince them that he was disposed to adhere to the treaty, he seized a large fleet of English merchant vessels, which, at his own request, had put into Copenhagen, in order to secure themselves from the Dutch fleet, which was cruising in the Sound. Cromwell was by no means disposed to put up with this treacherous conduct, and Bradshaw was accordingly sent to Copenhagen to remonstrate with Frederic. The Danish monarch seemed disposed to listen to Bradshaw. The Dutch were alarmed, and immediately consented to another treaty with him, by which they were to pay 150,000 rix-dollars, on condition that the king assisted them with a squadron of 20 sail. This squadron Holland did not demand; but by Denmark thus engaging in war with England, this latter power was prevented from getting her usual and regular supply of naval stores from the Baltic.

In 1655, the jealousies between Sweden and Denmark increased. Charles Gustavus was now on the throne of the latter kingdom, a monarch in the prime of life, of great and aspiring ambition, and of considerable enterprise and talents. Soon after his accession, he carried on a war in Poland, in which he was very successful. Frederic was alarmed at his conquests, and apprehensive that, if he possessed himself of the southern coasts of the Baltic, the Danish commerce would be greatly injured. Charles was at this time laying siege to Dantzic: Frederic and the United States, who were equally interested in stopping his further progress, agreed to send a united fleet. A Dutch squadron accordingly entered the Baltic; but Frederic delayed uniting his fleet to it, till he ascertained whether Charles was likely to be still successful. As soon as he heard that the Swedish monarch had met with some reverses, he determined to declare war; but he was surprised and embarrassed when the Dutch fleet returned home; and soon afterwards the United States concluded a treaty of peace with Sweden. He remonstrated against their conduct, but with no effect: the government adhered to the treaty; but the merchants fitted out private ships of war against the Swedes. This latter circumstance encouraged Frederic, who now openly declared war against Charles: an army was sent into Bremen, on which province he stated himself to have some pretensions; and the king sailed with a large fleet for Dantzic. The Danish army was defeated; and the fleet returned to Copenhagen without accomplishing any thing.

A. D. 1655.

War with Sweden.

The King of Sweden, on receiving intelligence of the Danish declaration of war, left Poland, and entered Holstein, where his progress was rapid; four regiments of Danes were made prisoners of war; the whole of this province was reduced, and he prepared to advance into Jutland. Before, however, he could do this, it was necessary to reduce the fortress of Frederics-Odde, which was remarkably strong and well garrisoned. Finding that the reduction of this place would require some time, he left Wrangel in command of the blockading army. This general, sensible of the great importance of its speedy capture, resolved, if possible, to carry it by assault. An hour before day-light, the assault was made, and the Swedes were masters of the place almost before the garrison were roused from their sleep. Frederic was not more fortunate by sea. The Swedish fleet, consisting of twenty-six men of war, fell

History.

in with the united Danish and Dutch squadrons; the action commenced and was continued with great obstinacy, but the Dutch deserted their allies; in consequence of this, the Danes gained only a doubtful and indecisive victory. The reputation, talents, and success of the king of Sweden, alarmed the United States, and several other of the powers of Europe; they were therefore disposed to assist Frederic against him; and Charles, sensible of this, determined to attack Denmark in its most vital part, and with all his force, before it was assisted. Accordingly, early in February, he crossed the Little Belt on the ice, entered the isle of Funen, defeated a considerable body of Danes, took Odensee, the capital of the island, and then resolved to march across the ice to Zealand. This bold and daring enterprize he accomplished, and marched immediately against Copenhagen. To defend the city, there were not more than 4000 men, consisting of 2000 horse, and 800 regular infantry; the remainder were made up of gentlemen, peasants, and sailors. General Krempen, who commanded this force, offered to set fire to the suburbs, attack the king of Sweden, who was at Keuck, and reduce that place to ashes. Frederic approved of the scheme, but it was rejected by the senate. The situation of Frederic in Copenhagen was extremely critical: the walls of the city were in a most ruinous condition; the supply of provisions, ammunition, and stores, was small; it was crowded with peasants, who had fled thither on the landing of the Swedish army, from all parts of Zealand; and the nobility were clamorous and discontented. Under the pressure of all these unpropitious circumstances, Frederic retained his firmness and presence of mind: his talents rose in proportion as they were required. In this emergency, he was greatly assisted by the prudent advice, and encouraged by the resolution and constancy, of his queen Sophia Amelia, princess of Brunswic-Luneburg. For nearly two years Copenhagen was blockaded by a powerful and victorious army; at length famine threatening the inhabitants, Frederic was induced to send a person to Torstrick, where Meadows, Cromwell's envoy, was endeavouring to negociate a peace. On the 28th of February 1651, peace was concluded, Frederic yielding up to the Swedes, Halland, Schonen, Blekingen, the island of Bornholm, the citadel and fief of Bohus, and the bishoprick of Drontheim. As the Swedish army was still in Zealand, Frederic was advised to refuse the cession of Schonen, till it was evacuated. This refusal irritated Charles, and he immediately sent part of his army to invest Copenhagen. Hostilities would have undoubtedly recommenced, had not the mediators interfered, and given the Swedish monarch such strong assurances of Frederic's sincerity, that an interview took place between the monarchs, on the most unsuspicious and friendly footing.

The Swedes blockade Copenhagen.

Peace concluded, A. D. 1651.

The greatest part of the Swedish army still remained in Zealand; and it was soon apparent, that the friendship of Charles was not to be depended upon, and that he was diligently in search of some plausible pretext for the renewal of hostilities. He complained, that Frederic had not complied with the treaty in some trifling points; and to enforce, or expedite compliance, as he alleged, he entered Holstein with his army. His ultimate object was for some time not suspected, till he persuaded the duke of Holstein to apply to the governor of Rendsbergh to put that fortress into his possession; on the governor's indignantly refusing to accede to this application, Charles landed his army in Zealand, and, with the forces already there, proceeded to block up all the roads leading to Copenhagen. A fleet at the same time blocked up the harbour; and on the 10th of September 1658, the rising grounds in the immediate vicinity of the city were occupied by a division of the Swedish cavalry and infantry. Frederic remonstrated against this gross and unprovoked infraction of the treaty; but Charles would scarcely admit the ambassadors sent on this occasion into his presence. This behaviour of the Swedish monarch made the nobility determined to lay aside their animosities, and to defend their monarch to the last extremity. It was also resolved to grant the burghers of Copenhagen certain important privileges, to induce them to support their sovereign, and cheerfully to endure the rigours of a siege. Their adherence to their sovereign was rendered still closer and firmer, by the condition to which the provinces lately ceded to Sweden were reduced; they were loaded with taxes, and the inhabitants were most grievously oppressed, both by the Swedish king and nobility. Frederic on this, as on the former occasion, was animated by the intrepidity, and assisted by the prudence of his queen; and he was so clearly convinced of the justice of his cause, and of his ultimate success, that he absolutely refused to comply with the advice of his council, and retire into Holland.

The Swedes invade Zealand.

Charles was fully persuaded that Copenhagen must soon fall into his power; and this confidence rendered him dilatory and unguarded. Frederic, on the other hand, was extremely vigilant; and he profited by the delay and oversight of his opponent, to prepare every thing necessary for a long and vigorous defence. The Swedes made their first attack on Cronenberg; and this place requiring a large force, and several weeks to reduce it, the siege of Copenhagen, in the mean time, was carried on with little alacrity or advantage. As soon as this fortress was reduced, Charles pushed the siege with great vigour; but he soon perceived that the defence wonld be both long and obstinate. He next turned his plans towards the reduction of the city by famine; but while part of his fleet was cruizing for the Dutch squadron, supplies of provisions were introduced into Copenhagen. Part of this city is built upon the isle of Amak, which is peopled by the descendants of a colony from East Friesland, to whom the island was given by Christian II. at the request of his queen, the sister of Charles V. for the purpose of supplying her with vegetables, cheese, and butter. It is entirely laid out in gardens and pastures, and the produce brought to the market of Copenhagen. This island Charles resolved to get possession of if he possibly could, and he accordingly made a sudden descent upon it at the head of large body of forces; he was opposed by Frederic, who sallied out of Copenhagen, broke through the Swedish lines, threw them into confusion, and obliged Charles to throw himself into a boat, and regain his fleet. The next day the Dutch fleet that had been sent to the assistance of their allies entered the Sound: Charles immediately ordered his fleet to oppose their advance to Copenhagen, and a most dreadful battle was the consequence, which terminated in the Swedes drawing off, under the protection of the cannon of Lanskroon, and in the Dutch admiral succeeding in his purpose of landing a large supply of provisions and ammunition, as well as a considerable reinforcement of men at Copenhagen. The Swedish monarch, disappointed at the issue of this battle, was soon afterwards alarmed by the advance of the elector of Brandenburg and the other allies of

Siege of Copenhagen.

Naval battle between the Dutch and Swedes.

Frederic into Holstein, where they gained several advantages. The militia of Norway also invaded Drontheim, which, by the last treaty, had been ceded to Sweden; and the people of this province still retaining their partiality for their native sovereign, it was soon reduced. However, neither the advance and success of the Danish allies, nor the conquest of Drontheim, turned Charles aside from his designs against Copenhagen; and in 1659, having concluded a peace with the Czar, he determined to make a vigorous and general effort to gain this city, before the frost should enable the elector of Brandenberg to pass over on the ice to Zealand. On the 10th of February, his measures being taken, and his preparations complete, he commanded the city to be stormed. In order to conceal the march of his troops on the snow, he ordered them to put shirts over their clothes, and they were thus enabled to come so near the besieged, as to touch them with their arms before they were perceived. Three attacks were made, but they were all unsuccessful: the first was led on by Steinboch, but his troops having lost all their officers, became daunted and fled; the second attack, led on by Colonel Smidt, had nearly succeeded on the side of the isle of Amak, when the Colonel was slain and his troops repulsed; Bannier, one of the most celebrated of the Swedish generals, commanded the third attack, but he was taken prisoner, and his division totally defeated. Charles, on this failure, might perhaps have been reduced to raise the siege, had not an English fleet arrived in the Sound, which prevented the Dutch admiral from throwing any more succours into Copenhagen; the blockade was therefore continued, and divisions of the Swedish army were sent into Langland and Laaland, which they reduced. Soon afterwards France and England offered their mediation for a peace; but there was such a great degree of exasperation and jealousy, and such opposing views and interests, that the negociations were very protracted and intricate: while they were carrying on, a cautionary clause was agreed to by the mediators, by virtue of which the Dutch fleet was permitted to enter Copenhagen, and thus in fact the siege was raised. The English mediator, perceiving that Charles was little disposed for peace, took his departure; and the Dutch being now at liberty to act in favour of Denmark, the Danes made a descent on Funen, and defeated the Swedes there with great slaughter. But the United States, whose interest it was not to permit either of the Baltic Sovereigns greatly to preponderate over the other, refused to permit their forces to enter Zealand, and assist the Danes to drive the Swedes completely out of it. Though hostilities had not been interrupted, the negociations for peace were still carried on; and Charles, perceiving that his projects were neither supported nor countenanced by England, while Frederic had been made equally sensible of the lukewarmness of the Dutch in his behalf, the two sovereigns became more sincere in their wish for peace. But Charles, though willing to accede to fair and honourable conditions, absolutely refused to give up Drontheim, on the cession of which the Danish commissioners most pointedly and strongly insisted; the war therefore would most probably have been renewed, had not the king of Sweden died. The French and English ambassadors took advantage of this event to bring about a peace between the two countries. By the articles of this peace, the fortress of Cronenberg, all the Danish islands in the Baltic, and Drontheim in Norway, were restored to Frederic; the isle of Rugen, the provinces of Blekingen, Halland, and Schonen, were given to Sweden.

Copenhageu stormed without success.

Peace restored.

Within a very few months after peace was concluded, Frederic effected a complete change in the constitution of the government of Denmark. By his conduct during the war, he had raised himself very much in the opinion of all classes of his subjects, for his firmness and his attachment to the interests of his country. But he was particularly dear to the common people: he had placed himself, in many instances, as a barrier between them and the insolent oppression of the nobles. The circumstances of the times, too, had rendered the nobility less formidable and powerful. Commerce had begun to produce its usual effects in Denmark as well as in other countries; it had rendered power and wealth more equal, by introducing new wants and desires among the privileged classes, and the ability to gratify them among those who hitherto had not been privileged, it brought them nearer to a level. Before, however, Frederic could take advantage of this state of things, it was necessary to investigate the condition of the kingdom; and it was found truly deplorable. The army had not been paid for a considerable length of time, consequently there was much dissatisfaction among the soldiers; scarcely any of the ships of war were fit to put to sea; and the public treasure was nearly exhausted by the avarice and extravagance of the nobility. To consider and remedy these evils, an assembly of the states was convoked on the 8th of September 1660. Notwithstanding the real power of the nobility was much curtailed, they were disposed to be as presuming and overbearing as formerly; but the citizens of the great towns now began to feel their weight and importance in the state, and particularly those of Copenhagen, to whom, as a reward for their patriotic and gallant behaviour during the siege, several of the rights of nobility had been granted.

Change effected by Frederic in the constitution of Denmark.

Frederic, aware of all these circumstances, determined, during the sitting of this assembly, to reduce the power of the nobles, and to extend his own power on the ruin of theirs. In this plan he was most zealously and successfully assisted by the queen, a woman not only of great fortitude, but of uncommon talents. She brought over to the king's party and interest, the field-marshal and some other noblemen; but she principally depended on the exertions and intrigues of the bishop of Zealand, the burgomaster of Copenhagen, Gabel a German, the king's private secretary, and also secretary to the privy council, and Lenthe, who was likewise a German. The first discussion in the diet respected the raising of the necessary supplies: the nobility proposed to lay a tax upon every thing that was consumed; and as a great mark of their condescending patriotism, offered to contribute equally to this tax; but when their offer was explained, it was found in fact to amount to almost nothing. They consented to pay this tax only when they were in town, and not at all while they resided on their own estates; nor would they subject themselves to it, even with this limitation, for a longer period than three years, while they insisted that the farmers should pay it as a permanent tax, and to its full amount. When the other orders began to remonstrate against this conduct, the nobility publicly and haughtily told them, that they ought to regard and receive it as a mark of the highest condescension, that they had deviated on this occasion from their established privileges. The clergy and the representatives of the

History.

people were indignant at this declaration, and they immediately proposed, in order to be revenged on the nobles, that all the fiefs of the crown should be let to the highest bidder, and that all classes should be deemed capable of holding them. Before this the crown lands had been rented exclusively by the nobility, who moreover paid for them only a very slight consideration. The nobles exclaimed most loudly and violently against the proposal, but the other orders were firm; and the friends of the king perceived that the moment was arrived for raising his prerogative and power firmly and permanently above those of the nobility. In this predicament the nobles acted with the utmost imprudence,; and the violent and overbearing conduct of one of them in particular, accomplished their ruin, and brought the plan of the king to maturity. In these diets, the nobility sat in a separate apartment from the clergy and the commons; but as it was necessary in discussing the nature and amount of the taxes, that a deputation from these two orders should attend the nobles, the bishop of Zealand, another clergyman, and the deputies of Copenhagen, were desired to attend; several others of the commons accompanied them unasked and unexpected: with this one of the senators, a proud and violent man, was offended, and he commanded all to leave the hall who had not been sent for. This behaviour increased their mutual jealousy and antipathy; and the clergy and commons determined no longer to communicate their plans or wishes respecting the subjects on which the diet was convoked, to the king through the senate, as had always been the custom, but directly to the sovereign himself. Frederic perceived immediately the advantage he might derive from this resolution, and he accordingly received the deputies of the clergy and commons in the most gracious and condescending manner. The nobility still persevered in their imprudent and rash line of conduct, and farther irritated the other orders, by materially altering a tax bill which had been sent to them. The bishop of Copenhagen, who was upon the alert to serve the king, immediately proposed to his order to sign a declaration, making the crown hereditary in the royal family. This proposal was readily accepted; the declaration was signed by the clergy, sent to the representatives of the people, who as readily gave their sanction to it, and on the very same day transmitted to the speaker of the nobles to have the concurrence of that order. The nobility were now alarmed and suspicious. They perceived that it was absolutely necessary to yield some points to the king, and by this reluctant yielding, they hoped to satisfy him; they, therefore, proposed to Frederic, that the crown should be hereditary in the male line only; but as the king was acquainted with the declaration that had been passed by the clergy and commons, he rejected the proposal of the nobles. On the next day, this order found itself under the necessity of acceding to the declaration, and a committee of the three orders was appointed by the king to carry the declaratlon into effect, by giving it the form and authority of a law. When this committee met, one of the members observed, that in all countries where the crown was hereditary, fundamental laws were established; and that as Denmark now was in that predicament, the committee ought to direct their attention to the passing of the necessary fundamental laws. This observation alarmed the friends of the king, whose object and wish it was undoubtedly to crush the power of the nobility, but not to limit the prerogatives of the crown.

Disputes between Frederic and the nobility.

The deputy, therefore, who moved the observation, was informed, that his future attendance on the committee would be dispensed with. The first point that occupied the committee, respected the capitulation which the Danish kings signed when they ascended the throne. As the constitution was about to be changed, it was necessary also to alter the articles of the capitulation. All agreed that certain articles should be omitted, and that others should be materially altered; but there was much difference of opinion, respecting the substitution of new articles, so that the capitulation might still be in fact a species of contract between the king and the people, and might define and limit his power: the nobles concluded, that their peculiar interests should be specified and confirmed in the capitulation; the clergy, on the other hand, not only objected to the claims of the nobility, but put in claims of their own. In the midst of the clamorous debates to which this difference of opinion gave rise, the Bishop of Zealand suddenly proposed, that the crown should be made hereditary, without any stipulation or condition; this was agreed to, with a trifling and unimportant exception, that the right of primogeniture, and the indivisibility of the monarchy, should be guarded. The capitulation which Frederic had signed at his accession, and which limited his authority, was restored to him, and the following day all the orders took a new oath of fidelity; but the three orders did not sign a separate act, consenting that the crown should be hereditary, investing the sovereign with absolute power, and giving him the right to regulate the succession and the regency, till the 10th of January 1661: and ever after this the new constitution was not explained or sanctioned by any promulgated law, till the accession of Christian V. in 1670. It was drawn up by the Bishop of Zealand and the count Griffenfeld, and received the king's sanction on the 14th November 1665, but was kept in the royal archives till the period above mentioned. The royal law, as it is called, consists of forty articles, of which the following are the most important: The hereditary kings of Denmark are above all human laws, and in all affairs, ecclesiastical or civil, they do not acknowledge any superior judge but God alone; the king alone possesses the right to make, repeal, change, and interpret all laws, except the royal law, which is irrevocable; the king shall be deemed of age at fourteen, and from that time he shall have no master or guardian; from the æra of the royal law, the kings of Denmark, so long as any branch of the royal family shall exist, will be born such, without having any occasion for an election; he shall not be obliged to take any oath, or enter into any engagement whatsoever respecting the monarchy, seeing that, as a free and absolute sovereign, his subjects can neither impose upon him the necessity of an oath, nor prescribe any conditions to him which shall limit his authority. The princes and princesses of the blood shall not appear before any inferior judge, because the king himself is their judge in the first and last instance. The 26th article is very long and very express on the subject of absolute monarchy: it declares, that every thing which may be said and written to the advantage of an absolute and hereditary Christian king, should also be understood in the most favourable sense of the hereditary king of Denmark; and it directs all his successors "to take very particular care to defend their hereditary right and absolute dominion, and not to suffer it to be called in question upon any condition whatever;" and if any person shall obtain any thing contrary to

the absolute and monarchical authority of the king, he shall be punished as having been guilty of the crime of high treason.

Consequences of the revolution in the government.

Many authors have contended, that, by this revolution, the people of Denmark lost their liberty; but the most superficial acquaintance with the history of this country previous to 1660, must convince us, that this opinion is entirely destitute of foundation. The people, in fact, were the slaves of the nobles; they were constantly degraded and oppressed by a number of petty tyrants. By the revolution they were freed from the power of these tyrants, though they were not raised to the rank and condition which they ought to hold in every well-regulated state. It may be a question, whether they were much benefited by the revolution, but there can be no doubt that it did not deprive them of their liberty. That the condition of the farmers was benefited is certain; for no sooner was Frederic invested with the supreme power, than he reduced the authority and humbled the pride of the nobles, by annulling several of their privileges, particularly that which gave them the power of life and death over their farmers. Many of the nobles resisted, and endeavoured to excite a rebellion; but their efforts were in vain, as the court took every opportunity to reduce their numbers and authority. In a very few years they were no longer formidable; the principal places of trust and emolument were kept from them. The laws protected the mass of the people against their oppressions, and the king exercised, with respect to them, the full authority with which the new constitution invested him.

Death of Frederic. A. D. 1670.

From the year 1660 till 1670, when Frederic died, he was almost occupied with the internal affairs of Denmark; he re-established the finances on an equitable and productive footing; gave encouragement to trade and commerce; and in a more especial manner promoted agriculture. In the midst of these wise and benevolent plans, he was carried off by a disorder, which he is supposed to have contracted during the siege of Copenhagen.

Christian ascends the throne.

The year before the death of Frederic, Christian, his oldest son, had been declared his successor at a general diet of the states. When he ascended the throne, Denmark, notwithstanding the plans of Frederic, was in a situation by no means prosperous. Most of the specie had been drawn out of the kingdom by the expences of the war, and the large subsidies granted to foreign powers; and the disputes which had arisen with Sweden, Holland, and Holstein, threatened the renewal of hostilities, and at any rate prevented the complete and regular adoption of any system of economy and retrenchment. The first object of Christian was to adjust his differences with Holstein; and this having been effected, he declared war against Sweden. Many reasons were given for this step. Sweden, ever since she was separated from Denmark, had encroached on the possessions of the latter kingdom; but a dispute respecting the Duchy of Bremen, was more particularly insisted upon by Christian, in his declaration of war. His principal allies in this war, were the Elector of Brandenburg, and the United States. With the former, the plan of the campaign of 1675 was arranged; and in conformity to it, his Danish majesty attacked and took the strong post of Damgarten, while his allies were employed in Pomerania. The next was a conjoint operation against the city of Wismar. Great and formidable obstacles here opposed themselves; but they were overcome by the perseverance and talents of Christian; finding that the marshes on which the besieging army was encamped, were unhealthy, he ordered them to be drained; and when this was proved to be impracticable, he kept his camp dry by dikes and ditches formed round it. The garrison held out with great obstinacy, and Christian at last resolved to carry it by storm; before the troops could arrive near enough for this purpose, it was necessary to march over the marshes, exposed to a galling fire from the garrison. In order to render the marshes passable, light wooden bridges were laid over them; and on these the troops proceeded three a breast. The fire to which they were exposed, at first daunted and checked them; but animated by the example of their sovereign, they proceeded, and in the space of a few hours the governor capitulated. After the reduction of this place, Christian meant to have invaded the isle of Rugen; but he was drawn aside from this scheme, in consequence of false information that the Swedes were preparing to make a descent on Zealand. In consequence of this, he returned to protect his capital. The next enterprize of Christian and his allies, was the reduction of Stade, which city fell into their possession after a long but not a very active or obstinate defence. Hitherto the fleets of the hostile powers had not met; but in the beginning of June, the Danish fleet having been reinforced by some Dutch ships, after having conquered the isle of Wisby, fell in with the Swedish fleet between the coast of Schonen and the isle of Bornholm. An action commenced, which continued, at intervals, for two days, but terminated without any advantage to either party. In this engagement the Swedes possessed the superiority in point of numbers; but a few days afterwards, the Danish admiral having been reinforced by four Danish and three Dutch men of war, under the command of the famous Von Tromp, again proceeded in quest of the Swedes. On the 11th of June, the battle began; in a very short time the Swedish admiral's ship, which is said to have carried 134 pieces of brass cannon, and 1100 men, was blown up. On this the rest of the fleet endeavoured to escape, but being surrounded by the Danish and Dutch vessels, they gave up this idea, and fought with astonishing intrepidity; but situated as they were, their intrepidity was of little avail; ten of their ships, besides some small vessels, fell into the hands of their enemy. The immediate consequence of this victory was, the reduction of Stade, which has been already noticed; and the resolution, on the part of Christian, to invade Schonen. While the Swedes were superior, or even equal to the Danes by sea, this invasion was impracticable, but now it could be easily effected, and promised to be attended with complete success. As soon as Christian entered this province, he ordered Von Tromp to attack the city of Ustadt, which, after a short but obstinate defence, was evacuated by the garrison. The Danes lost no time in following up their success, and Christianstadt, Helsingburgh, and Landscroon, were reduced. Charles the Eleventh, King of Sweden, alarmed at the progress and success of the Danes, collected a large army, surprized three thousand men under General Duncamp, and totally routed him. Christian, on the intelligence of this disaster, marched himself against the Swedes, who retreated in a rapid manner before him, so that he could not come up with them. In order to draw them on to an engagement, he laid siege to Malmo. As it was of the utmost consequence to relieve this place, Charles, at the head of 18,000 men, encamped on the opposite side of the river, which divided the two armies. He soon found, however, that the direct relief of Malmo was

Declares war against Sweden.

A. D. 1675.

Naval battle between the Danes and Swedes.

History.

impracticable, and therefore breaking up his encampment, he proceeded to lay siege to Helsingburgh. This brought on the battle of Lundin, which, though not decisive in its actual and immediate consequences, ultimately proved advantageous to the Swedes, by enabling them to relieve Malmo. In the mean time, negotiations were going on at Nimeguen for a general peace, and the Danish and Swedish ambassadors attended the congress there; but while the other European powers seemed disposed to reconcile their differences, Sweden and Denmark made such unfair and exorbitant claims on each other, and betrayed such a great degree of mutual jealousy and suspicion, that preparations were soon made for prosecuting the war between them with renewed vigour. The Danes resolved to make another attempt to gain possession of Malmo; but owing to the accidental breaking down of the draw-bridge, just as they hoped to attain their object, they were repulsed and compelled to raise the siege. By sea, the King of Denmark was more successful. A Swedish fleet lay at Gottenburgh, which the Danish admiral attacked with great fury, and with such success, that six of the Swedish ships were taken. The Swedes eagerly sought an opportunity to wipe away this disgrace; and learning that the same Danish admiral was lying near the isle of Mona, it was resolved to attack him with greatly superior numbers, under the command of some of the best officers in the Swedish navy. In this battle, the Danish admiral made up, by his skilful manœuvres, for his inferiority in respect to numbers. He broke the line of the enemy, and threw them into such confusion that they were not able to fight to any advantage. The consequence was, that seven of their ships were taken or destroyed. Nearly at the same time the Danish and Swedish armies met, each commanded by its king. The Swedish army was nearly double that of Denmark; but Christian was not dispirited; he fought with the utmost bravery, and his example was followed by his whole army; so that the only advantage which the Swedes gained was that of keeping the field, the Danes retreating to their camp in good order. In Norway the war was prosecuted with great vigour, and with various success, though on the whole the Danes gained more brilliant, as well as more substantial, advantages than their opponents. In Pomerania they were not so successful. After Count Konigsmark had been compelled to abandon Rugen, he retired with his army to the neighbourhood of Stralsund: here he meditated the reconquest of the isle, and for this purpose requested and obtained the assistance of the burghers of Stralsund. The Danish governor, not supposing that Konigsmark was in a condition to act on the offensive, was careless and unguarded, and did not even dispute his landing on the island: as soon as he was landed, he marched against the Danish army, which was encamped at a distance from the shore. At the very commencement of the battle, the Danish governor was slain; disputes arose among the inferior officers, subordination was destroyed, confusion took place, and though part of the Danish forces broke through the left wing of the Swedes, they were compelled to retreat, and 5000 men were made prisoners. While his general was thus victorious in Pomerania, the Swedish monarch was actively employed in besieging Christianstadt. Christian marched to the relief of this place, at the head of 12,000 men, but all his attempts were frustrated; he could not expect to succeed unless he defeated the Swedes; and they, strongly intrenched, would not quit their camp; Christianstadt, therefore, was forced to surrender in sight of the Danish army.

Battle of Lundin.

Naval battles.

As some compensation for the loss of this place, the Danish admiral planned a descent on the isle of Rugen, and succeeded in retaking it, and in reducing Stralsund and some other places in Pomerania. Soon afterwards, the negociations at Nimeguen were resumed; and Christian, being forsaken by his allies the Dutch and the Elector of Brandenburg, ordered his minister to sign a peace with Sweden, in the month of September 1679. By this peace, the King of Sweden obtained all that he claimed before the war, and Christian was obliged to submit to those terms which were dictated by France, in consequence of the defection of his allies. Holstein Gottorp was restored to its Duke; and the treaties of Roschild, Copenhagen, and Westphalia, were declared in force between the courts of Denmark and Holstein. While the negociation was pending, Christian marched a large army into the neighbourhood of Hamburgh, under the pretence of disputing the passage of the Elbe with the French general, who was advancing to support the Swedes. The people of Hamburgh were alarmed, and suspecting Christian's designs to be hostile to them, they fortified their city. Christian, upon this, avowed his purpose in a manifesto, in which he laid claim to Hamburgh: and immediately laid siege to it; but Louis the Fourteenth interfering, and the Duke of Brunswick having sent a body of troops to defend the city, a treaty was concluded, by which Christian renounced his claims, on the payment of a certain sum of money. In 1680, the hostility which had so long existed between Sweden and Denmark, and which, even during peace, had frequently manifested itself, by mutual jealousy, was for a time suspended, by the marriage of Eleonora, princess of Denmark, with his Swedish majesty. Christian, still having views on the city of Hamburgh, learned, with much satisfaction, that the senate and the people were at variance, in consequence of the latter having refused to pay the taxes laid on by the former. The disputes ran so high, that all government ceased; and no opposition to Christian's schemes seemed likely to arise. He therefore advanced with a powerful army; but his presence and threats united the senate and the people. His proposals were rejected, his attacks repulsed, and he was obliged to desist from his designs against this city. Few events of importance occurred from this time till the death of Christian. He took advantage of the expiration of the treaty of commerce between Denmark and Holland, to raise the Sound dues; this was opposed by the Dutch, and Christian was obliged to yield. In 1689, a treaty was concluded at Altona, by which he consented to confirm Duke Albert in possession of Sleswick and Holstein, of both of which he had defrauded him some time before. In 1699 Christian died, in the 54th year of his age, and 29th of his reign.

Peace concluded. A. D. 1679.

A. D. 1680.

Death of Christian. A. D. 1699.

Christian was succeeded by Frederic the Fourth. This prince was tempted, by the extreme youth of Charles the Twelfth, King of Sweden, to commence hostilities against that monarch; but as he had no direct ground for a war with Sweden, he renewed his claims to Holstein, the duke of which had married the sister of Charles the Twelfth. Accordingly he invaded this province, and laid siege to Tonningen. Charles lost no time in assisting his relation; he sent 8000 men into Holstein, and, at the same time, he himself, at the head of 20,000 men, landed in Zealand, and laid siege to Copenhagen. The inhabitants,

War with Sweden.

in the absence of their sovereign, sent deputies to Charles, to request that he would not bombard the town; to this request he gave his consent, on condition that they paid him immediately about 80,000 pounds, and brought regularly to his camp all kinds of provisions, for which, however, he engaged to pay punctually. As soon as Frederic learned that his capital was in such imminent danger, he published an edict, in which he promised freedom to all those in every part of his dominions that should take up arms against the Swedes. Charles, upon this, informed his Danish majesty, that he only made war to oblige him to make peace; and that he must resolve to do justice to the duke of Holstein, or to see Copenhagen destroyed, and his kingdom laid waste by fire and sword. Frederic eagerly accepted the conditions, and the peace of Travendahl was concluded, by which the full right and sovereignty was confirmed to the duke of Holstein. His Danish majesty agreed to pay him 260,000 crowns; and liberty was given to the chapter of Lubeck, to elect, as their bishop, a prince of Holstein.

While Charles the Twelfth was victorious, this treaty was faithfully observed by Frederic; but fortune having deserted the former monarch, and the duke of Holstein having been killed in 1702, Frederic again invaded this province. Steinboch, one of Charles's best generals, had thrown himself into Tonningen, and Frederic made this a pretext for the renewal of hostilities, and the whole province was occupied by his

A. D. 1720. troops. In 1720, however, he entered into a treaty with the young duke Charles Frederic, by which he kept the whole of Sleswick, and restored only part of Holstein. The reverses of the king of Sweden also prompted Frederic to invade Schonen: At this period Sweden was in a state of great disorder; the senate, and the regency whom the king had established when he left Stockholm, were at variance; but as soon as they heard that their country was invaded by the Danes, all their animosity and disputes were forgotten. There were only 8000 regular troops in the kingdom; to these Steinboch united about 12,000 militia, and came up with the Danes, who were ravaging the country in a most barbarous manner, near Helsinburgh. He did not intend to have attacked them immediately, but his militia were so eager to engage, that he altered his plan; and two regiments of those farmers, who had only taken up arms three weeks before, fought with so much intrepidity, that they destroyed nearly all the king of Denmark's guards, so that scarcely ten of them escaped. The Danish army was entirely defeated, and retired under the cannon of Helsinburgh. A few days after this disastrous battle, the remains of this army quitted Sweden with great precipitation, killing all their horses, setting fire to their provisions and baggage, and leaving 4000 wounded in the town, all of whom died for want of food, the Danes having laid

A. D. 1711. waste the country round Helsinburgh. In 1711, Frederic invaded Swedish Pomerania; but though he was assisted by the Poles, he gained little advantage by this invasion, except the reduction of Damgarten. In the following year, he conquered the duchy of Bremen, and took the city of Stade; but the Swedish army advancing against him, he was defeated with considerable loss, and the town of Altona burnt to the ground. The Swedes afterwards having invaded Norway, Frederic proceeded to the defence of that part of his dominions, and compelled them to retreat with great loss. Charles the Twelfth was still absent from his country; and the allied powers, Poland, Prussia, Denmark, and George the First as elector of Hanover, attacked the Swedish possessions on the east side of the Baltic; the reduction of Wismar was entrusted to Frederic, and he succeeded in effecting it. Soon after Charles returned to Sweden, he raised and disciplined a large army; with which, though his own country was threatened on all sides with powerful and victorious enemies, he suddenly invaded Norway. In this kingdom there were only 11,000 troops; so that Charles soon made himself master of the greatest part of it: He had advanced near to Christiana, but as he had taken no precaution for the support of his army, he was obliged, from want of provisions, to retire into Sweden. In the

A. D. 1718. month of October 1718, Norway was again invaded by Charles; but the kingdom was saved by the death of that monarch at the siege of Fredericshall, on the 11th of December; upon which the Swedish army returned into their own country. The war between the two powers continued with various success, but presenting no event of importance till 1720, when peace was concluded, under the mediation of George the First. The principal article in this treaty secured the possession of the duchy of Sleswick to Denmark, under the guarantee of France. Between this period and 1730, when Frederic died, the kingdom was tranquil and flourishing: The only circumstances which impeded its advancement in prosperity, were the destruction of a great part of the capital by fire, and the disposition of Frederic to lay out the public money on impracticable or unprofitable schemes.

Peace concluded. A. D. 1720.

Christian VI. ascends the throne.

Christian Frederic, better known under the appellation of Christian the Sixth, succeeded his father Frederic the Fourth. During nearly the whole of his reign, Denmark enjoyed a state of profound peace; and Christian took advantage of this circumstance to improve his territories and benefit his subjects: hence no sovereign is a greater favourite with the Danish people. Several monopolies existed, some of which were extremely prejudicial and obnoxious to the nation at large; these he either totally abolished, or regulated and restrained in such a manner, as to diminish and limit their evil consequences. In particular, he abolished a farm, which he had established during the reign of his father, among his other speculations, for the exclusive sale of brandy, wine, salt, and tobacco. In the abolition of this farm, he displayed not only his wise and comprehensive policy, and his regard for the interests of his people, but also that exclusive or paramount regard to their interests, which too seldom is found to actuate the conduct of princes; for this monopoly was not more oppresive to his subjects, than it was lucrative to himself. When the persons to whom this monopoly had been granted, offered to give him large sums of money, provided he would permit it to be continued, he replied, "It produces too much, since my subjects complain of the exactions it occasions."

His regulations in favour of trade and commerce.

The disputes which had so long subsisted between Hamburgh and Denmark, and which more than once had broken out into bitter and rancorous hostility, were brought to a complete and advantageous termination by Christian; he indeed managed this business with so much adroitness, as to induce the people of Hamburgh to consent to pay him a large sum of money, and to grant several privileges which were highly beneficial to the trade and commerce of his subjects. But his attention and thoughts were in a more especial manner directed to render his country powerful, rich, and happy; in order to effect this, he established a council of trade, composed of men whose experience

History.

and information rendered them most fit and proper for this situation; their duty was carefully to examine every proposal made for the extension of commerce; to suggest, of themselves, whatever they thought would benefit it; and to give the necessary encouragement to such plans as met with their approval. Into some of his schemes for the extension of trade and commerce, we may perhaps perceive that error to have crept, which is too often committed by sovereigns and statesmen; he thought that his own country ought and might supply itself with every thing; or at least that it would be better to produce what was necessary or wanted at home, though at a greater expence, than import it from foreign countries. The royal bank of Copenhagen owes its origin and establishment to him; and from it trade derived many advantages, by the facility which it afforded of raising and disposing of money. The army and navy were not neglected: in order that he might be enabled to put them on a respectable footing, without oppressing his subjects with taxes, he entered into subsidiary treaties with foreign powers. In rebuilding Copenhagen, he paid particular attention to the convenience and healthiness of the place; and the royal palace was rebuilt in a style of elegance, which displays considerable taste in architecture.

During the whole of his reign, he had only two disputes with foreign powers; one with the king of Great Britain, as elector of Hanover, in 1738, respecting the lordship of Steinhorst, in which some blood was spilt; but Christian carried his point so far, as to receive a subsidy of L.70,000 a year from Great Britain, on condition that Denmark kept 7000 troops on foot for the protection of Hanover. The other dispute in which he was engaged, respected the Iceland fishery, to which the Dutch made some claims, which Christian thought unfounded; this also terminated to his advantage and honour; and in both cases, he discovered great firmness united with moderation, and a degree of policy and prudence, which enabled and disposed him to conduct the dispute in such a manner, as insured such a result as he desired. He died in 1746, after a happy and prosperous reign of sixteen years, and was succeeded by his son Frederic the Fifth.

Death of Christian. A. D. 1746.

Frederic V. ascends the throne.

In 1743, Frederic had married Louisa, daughter of George the Second. He was very fortunate in two of his ministers, Count Bernstoff, and Count Schimmellman, both noblemen of very superior talents and information, and anxious to employ them for the benefit of their sovereign and his subjects. Under their guidance, Frederic applied himself to carry on the plans which his father had begun, and by the assistance of the latter nobleman, more particularly, the finances of Denmark were completely restored to order, and the taxes were rendered lucrative, without being burdensome or oppressive to the people. One of his first objects was the regulation of his domestic economy, which indeed had been begun by Christian: into it he introduced much retrenchment, and established it in such a manner, as secured order and method, and enabled him to detect and put a stop to any extravagance, or unfaithfulness, on the part of his household. At first his subjects were rather apprehensive that this minute and scrupulous attention to his domestic economy proceeded from, and indicated a narrow and parsimonious disposition, but they were soon convinced that their welfare alone was his motive and object; he was saving and economical himself, in order to render their condition more comfortable. That he was not mean or avaricious, was most clearly and honourably shewn by his behaviour, when a great mortality happened among the cattle, on some of the crown estates; he immediately, and unsolicited, remitted his just rights; and whenever famine oppressed or threatened his people, he stepped forth to their relief. By the order and economy which were introduced into the finances, he was enabled, not only to encourage trade and manufactures, and to keep his fleets and armies on a respectable footing, but also to pay off a considerable part of the debt which had been contracted by his predecessors. An anecdote is told of Frederic on this occasion, which deserves insertion, as displaying his character to great advantage. When the creditors of the crown learned that he had determined to pay off the debt, they endeavoured to dissuade him from his purpose, by promising to lower the interest from 5 to 4 per cent.; to this the king replied, that as he had money in his coffers, where it could be of no use, he preferred paying off the public debt; but he should esteem it a personal favour if they would lend the money to his subjects at the interest at which they had offered it to him.

Frederic, like his father, was of a pacific disposition, and he conducted himself with so much prudence, as to keep clear of the seven years war, in which almost all the powers of Europe were entangled. His connection with the king of England, however, led him to offer his mediation, when the Duke of Cumberland was unsuccessful: and it was through that mediation that the treaty of Closterseven was agreed upon. The end of his reign was not so fortunate as the beginning of it: Peter Ulric of Holstein had ascended the throne of Russia; and soon afterwards laid claim to the whole of that province, and also to the Duchy of Sleswick. Frederic, alarmed at the prospect of a war with Russia, was persuaded to employ a French officer, for the purpose of introducing the new tactics into the Danish army: the Danish soldiers were strongly averse to any change, and more especially averse to it, if introduced or recommended by a foreigner; the French officer, with that vanity, rashness, and presumption so common among his countrymen, paid no attention to the murmurs, or even to the expressed discontent of the soldiers: he still proceeded with his reforms, till the safety of the kingdom absolutely required his removal, and the restoration of the established discipline. While these things were going on, a Russian army, under General Romanzow, entered Holstein, and it is probable that this province would have been wrested from Denmark, had not the Emperor Peter been suddenly taken off: Catherine, who succeeded him, immediately recalled her troops, and a negociation was entered into, respecting the exchange of part of Holstein for Oldenburgh and Delmenhorst, but it was not completed when Frederic died, on the 14th of January 1766.

Death of Frederic. A. D. 1766.

Christian VII. ascends the throne.

The commencement of the reign of his son Christian VII. was auspicious; all the peasants on the crown lands, who hitherto had been in a state of most abject vassalage, were emancipated by the first edict which he issued. The negociation with Russia respecting Holstein was resumed, but it could not be finally adjusted, till Paul Petrowitz, who was heir to the German possessions of Peter, attained his majority. This event did not happen till the year 1773, when a treaty was signed, by which the counties of Oldenburgh and Delmenhorst were ceded to the grand duke of Russia, and the king of Denmark, as a compensation, was put in possession of the whole of Holstein.

Frederic V. after the death of his first wife, by

History.

whom he had Christian VII. married a daughter of the duke of Brunswick Wolfenbuttel; this princess was of an ambitious disposition, and was not restrained by any sense of justice, or feeling of moderation, from pursuing those measures to which her ambition prompted her. She had by her husband a son named Frederic, and her most anxious wish was to place him on the throne, after the demise of Christian; but Christian had married Matilda, the youngest sister to George III. and as issue was likely to proceed from the marriage, the Queen-dowager was afraid that her favourite scheme would be defeated. She, therefore, in the beginning of January 1772, formed, along with her son, a strong party at Copenhagen, who commenced their intrigues, by endeavouring to create dislike and mistrust between the king and queen. Their first plan seems to have been to have infused into the mind of the queen a disgust of her consort; and, for this purpose, the king, who was a man of a very weak mind, was surrounded by persons who kept him in a constant state of debauchery, and who took care that the queen should be perfectly acquainted with his behaviour. Matilda, however, either suspecting their designs, or indifferent about the manner in which the king conducted himself, paid no attention to their representations. The queen-dowager perceiving that the scheme they had hitherto pursued would not answer, determined to excite the suspicion and jealousy of the king against his spouse; and the unguarded behaviour of Matilda unfortunately afforded her the opportunity she wished for. She manifested an improper partiality for count Struensee: this nobleman had been originally a German physician, who, having ingratiated himself into the favour of Frederic, had been raised to the dignity of a count, and appointed his prime minister. He had neither talent, strength of mind, nor prudence sufficient to conduct himself properly in his new situation, but alarmed and disgusted the old nobility, by the unnecessary and injudicious reforms which he attempted to introduce. To this unpopular and weak man Matilda discovered an evident partiality; and on this circumstance the queen-dowager built her plans. The king was persuaded that his consort, in conjunction with Struensee and his friend count Brandt, had formed a design to set him aside, on the pretext of incapacity, and of course, according to the royal law of 1660, to declare the queen-consort regent during the minority of his successor; they suggested to him the absolute necessity of immediately signing an order for confining the queen and her associates in separate prisons; but they met with much opposition and reluctance. It was, therefore, advisable to conduct this part of the business with more caution, and to wait for a favourable opportunity of still farther exciting the suspicion and jealousy of the king against his consort and Struensee. This opportunity offered itself on the 16th of January. On the evening of that day, a masked ball was given at court, from which Matilda, after having danced the greatest part of the night with Struensee, retired about two o'clock in the morning. The queen-dowager and prince Frederic, who had undertaken to surprise the king and make him sign the order, entered his apartment soon after Matilda had left the ball room, waked his majesty out of his sleep, and told him that his consort and the count Struensee and Brandt, were at that very moment drawing up the act of renunciation, which they would compel him to sign; and that if he wished to save himself, he must give instant orders for their arrest. Frederic still hesitated, till they actually threatened him into compliance. The queen-consort was immediately taken out of bed, and with her infant princess conveyed to the castle of Cronenberg, while counts Struensee and Brandt were confined in separate dungeons, and treated with the utmost severity. An extraordinary commission was appointed to try the supposed criminals. The queen was accused of a criminal conversation with Struensee; and this nobleman was accused of having abused his authority, and of having applied a great part of the public money to his private emolument; but no witnesses were found to substantiate either of these charges, or the more heinous charge of having had designs to deprive the king of his authority. The queen-dowager, however, resolved to proceed; and though, by the laws of Denmark, the torture was forbidden to be used for the purpose of extorting confession, yet Struensee was threatened with it, unless he confessed every thing that was demanded of him respecting the queen. The fear of the rack produced from him the confession which the queen-dowager wanted; he acknowledged that he had been intimate with the queen. Struensee and his friend Brandt, after having been under examination nearly two months, at last received sentence: the sentence of the former states, that he had confessed himself guilty of a crime, which comprehended the crime of treason in the highest degree; and that he had defrauded the king, and applied the public money to his own use. The last accusation they had not been able to substantiate by witnesses, nor had Struensee acknowledged its truth; but by obtaining possession of his private papers, it appeared that he had made a charge of 120,000 rix dollars for an article of expence, which could not amount to 20,000 rix dollars. When Struensee was examined on this head, he acknowledged that the papers were in his hand-writing, but that this charge, as well as several others, had been falsified by some other person. The sentence of Brandt accused him of having given the king a blow, and otherwise ill treating him. They were both condemned to be beheaded, after having their right hands cut off: the sentence was carried into execution on the 28th of April 1772. The English court interfered in behalf of the queen consort; and she was liberated from her confinement, and permitted to spend the remainder of her life at Zell, in Hanover. The queen-dowager having thus accomplished part of her object, by means, however, which excited great indignation, placed about the king count Guldberg, one of her associates. In order to draw off the public thoughts from the recent transactions, this minister passed several laws much in favour of the great body of the people, particularly one law which gave to the natives of Denmark very special privileges, and which was declared to be a fundamental law of the kingdom.

Intrigues of the Queen-dowager. A. D. 1772.

Execution of Struensee and Brandt, A. D. 1772.

In 1780, Denmark, persuaded or intimidated by the empress Catherine, joined the armed neutrality of the North. From this time till the year 1784, nothing remarkable happened; the king's imbecility of mind grew every day more apparent, and intrigues were set on foot to take advantage of it. The king of Prussia, who was nearly related to the queen-dowager, by her means, gained an almost absolute sway in the cabinet of Denmark; the only minister who opposed his views was count Bernstoff, and he was soon dismissed from his employments, and obliged to retire into Germany. But in order still farther to strengthen his party, it was

Denmark joins the armed neutrality of the North, A. D. 1780.

History.

necessary to keep the prince royal out of the privy council. By the laws of Denmark, he could not be sworn in a member till he had taken the sacrament, and he could not take the sacrament till he had undergone a public examination; this the ruling party contrived to put off, under the pretext that he was not yet sufficiently well instructed in religion. As soon, however, as he arrived at the age of 16, they were obliged to consent to his admission into the privy council; and the first step he took was to advise the king to dismiss his ministers, and to reinstate count Bernstoff. The other party endeavoured to intimidate him; but he was resolute, and carried his point. A new council was formed; and as they apprehended that the queen-dowager might again take advantage of the king's imbecility, they passed an order, that no instrument signed by him should be valid, unless it were countersigned by the prince. One of the first acts of his administration rendered him extremely popular; he completely emancipated all the peasants on the estates of the crown, with so much prudent and cautious preparation, that no evil consequences resulted from this change on their condition. His example was followed by some of the nobility, but by no means to the extent that he wished or expected. The slave trade was also abolished, principally by the advice and exertion of count Schimmellman, who himself possessed large estates in the West Indies.

Denmark joins the northern confederacy against Britain, A. D. 1801.

For a considerable time after the commencement of the French revolution, Denmark remained tranquil, wisely refusing to engage in the wars produced by that event. At length in 1801, the madness of the emperor Paul obliged her to accede to the confederacy against Great Britain, formed by Russia and Sweden. In consequence of this, Great Britain sent a formidable fleet into the Baltic, the transactions of which against Copenhagen have been already fully detailed in the article Britain. The defeat of the Danes, and the death of Paul, dissolved the confederacy; and the Danish possessions in the East and West Indies, of which the British had captured, were restored. When the war between Britain and France recommenced in 1803, Denmark resolved, if possible, to adhere strictly to her system of neutrality; but it was soon apparent that the success of the latter power in Germany would place her in a perilous situation, or compel her to take an active part in the contest. But she escaped till the year 1807, when the peace of Tilsit convinced the British cabinet, that Denmark, even if she were well disposed to resist the importunities of France to unite herself against England, was no longer capable of acting as an independent power; they also knew that France was determined to gain possession of the Danish fleet, either by intrigue or force. These considerations induced them to propose to the Crown Prince to surrender the Danish navy into the hands of Great Britain, to be restored at a general peace; this proposal the Crown Prince indignantly rejected, declaring that he was both disposed and able to maintain his neutrality, and to defend his kingdom against any power that durst attack it. The British ministry, having failed in the negociation, resolved to have recourse to force. A strong expedition was accordingly sent out against Copenhagen in the month of August 1807: the operations and result of this expedition are given in the History of Britain. After the British ministry had gained their object, they endeavoured to conciliate the Crown Prince; but he was so exasperated at the bombardment of his capital and the seizure of his fleet, that he would listen to no terms, but declared war against Great Britain, and soon afterwards against Sweden as the ally of Britain. By this conduct he threw himself completely into the arms of France; and in March 1808, Marshall Bernadotte arrived in Zealand for the purpose of organising the Danish army, and concerting measures for the defence of the island, and for the invasion of Sweden. Soon after his arrival, Christian VII. died, and the Crown Prince was proclaimed king by the name of Frederic VI.

Expedition against Copenhagen, A. D. 1807.

Death of Christian VII.

The determination of Denmark to unite herself with France, gave satisfaction to Bonaparte on several accounts; it afforded him a pretext for sending a large army into Zealand, and the other Danish islands, and the probable means of transporting it to Sweden: could he effect this latter object, he would have possession of the Sound, and consequently could shut out Great Britain from the Baltic. He, therefore, encouraged Frederic in his hostile intentions against Sweden; and nearly 30,000 troops, Spanish, French, and Dutch, were assembled in Zealand; but owing to the watchfulness of a strong English squadron, the invasion could not be attempted. In the mean time, Sweden invaded Norway; but the obstacles presented by nature, and the determined resistance made by the Norwegian militia, and a few regular Danish troops, prevented them from succeeding in this enterprise. Hostilities between Great Britain and Denmark were carried on with great rancour, though on a small scale; there were frequent engagements in the Baltic and on the coasts of Norway, with the Danish gun boats and the British cruisers, in all of which the former fought bravely, and in some of which they were victorious. In the East and West Indies, Denmark was deprived of her possessions; and the small isle of Heligoland, at the mouth of the Elbe, was occupied by the British. The principal object in reducing this island was to make it a depot for manufactures and colonial produce, which might thence be easily introduced into the continent, in spite of Bonaparte's decrees and precautions against British commerce. A similar reason induced the British ministry to take possession of the isle of Anholt in the Baltic: the loss of this island irritated the Danish government so much, that they resolved to attempt its recapture. For this purpose, in March 1811, a large armament, consisting of 3000 men and 12 gun-boats, was equipped. The garrison of Anholt amounted only to about 400 men, under the command of Captain Maurice of the navy. The British commander, apprised of the meditated attack, took his precautions with a great deal of judgment; he intended to have opposed the landing of the Danes, but this they effected before he was aware, being favoured by a thick fog. As soon as they were landed, they attempted to outflank the British, or, by threatening it, to compel them to fall back into the fort: in this they totally failed, and being at the same time attacked by some British cruisers, they were obliged to retreat with great loss. Part of the Danish army had advanced against the fort, and even gained the outworks, but they also were repulsed, and their commander killed. This event threw them into confusion, by which Captain Maurice profited, and upwards of 400 of them were made prisoners. As this was a larger number than the whole of the garrison, Captain Maurice was under the necessity of permitting the rest of the Danes to reimbark.

The isle of Anholt taken by the British, A. D. 1811.

But the injury inflicted by Great Britain on Denmark was much more serious and extensive than that which resulted from the capture of her islands; her

History.

Annihilation of Danish commerce.

commerce was nearly annihilated, her finances were in a state of confusion and embarrassment, and Norway, cut off by the British cruisers from the possibility of gaining her necessary and usual supplies from Denmark, suffered under a scarcity approaching to famine. Still the remembrance of the bombardment of Copenhagen, but more especially the dread of Bonaparte, kept the Danish government back from offering, or acceding to, any reconciliation with Great Britain. Such was the state of things when Bonaparte lost nearly the whole of his army in Russia: he was considered as no longer formidable; and Denmark seemed disposed to profit by this circumstance to make peace with England. To this she was probably induced by another consideration; Sweden, her ancient rival, was in alliance with England, and she justly apprehended that this alliance boded her no good. An ambassador was therefore sent over to the court of St James, but without success, as the terms of the alliance between that court and Sweden, by which Norway had been in a manner guaranteed to the latter power, were incompatible with a reconciliation between England and Denmark. That the Danish government were anxious for this reconciliation, they sufficiently manifested by protecting Hamburgh against the French, with whom they were still in alliance; on the failure, however, of their mission to the British court, they withdrew their protection from Hamburgh, and united their forces to those of France.

After the reduction of Hamburgh by Marshal Davoust, the Danish forces, which were attached to his army, were inactive for some weeks, in consequence of the armistice which had been concluded between France and the allied powers. But on the recommencement of hostilities, in the middle of August, Davoust, with the Danes, marched into Mecklenburg. The object of his movements and operations, was to assist the French corps under Oudinot, in their attack on Berlin, which was protected by the Crown Prince. The advance of Davoust, however, was very slow and difficult; the allied troops in Mecklenburg, under the command of Count Walmoden, being able to check and retard his progress. With them he had several skirmishes, in which the Danes fought with great bravery, and suffered considerably.

It is probable that Davoust might have succeeded in uniting his forces with those of Oudinot; but the latter having been defeated by the Crown Prince, and Marshall Ney, who, after this defeat, was sent by Bonaparte to take the command of Oudinot's corps, having suffered a still more decisive defeat by the Crown Prince at the battle of Juterbock, Davoust thought it prudent to retrace his steps towards Hamburgh.

The important battle of Leipsic, on the 19th of October, rendered it absolutely necessary for Davoust to consult the safety of the army under his command; and he accordingly took up a strong position on the Steignitz. The Crown Prince having liberated Hanover, marched against him, in order to recover Hamburgh, and if possible to detach the Danish troops from him, and compel or persuade the King of Denmark to make peace. He succeeded, without much difficulty, in dislodging Davoust from the Steignitz. No place of refuge now remained for him but Hamburgh; and into this city he threw himself and the French division of his army, leaving the right wing of the Danes entirely exposed to the attack of the Crown Prince. Thus forsaken, they were attacked and defeated in two actions, in the beginning of December, by Count Walmoden, and the Swedish troops. In one of these actions, the most desperate bravery was displayed by two Jutland regiments. They had suffered considerably during the campaign in Mecklenburg; and in consequence of their losses, they had taken an oath to support each other, and neither to give nor receive quarter in any subsequent battle in which they might be engaged. This agreement, they most inviolably kept; rushing on the allies with indescribable fury, not more than 400 of them escaped.

History.

Armistice, A. D. 1813.

Nothing now opposed the Crown Prince in his conquest of Danish Holstein, which he overran in the course of a few days, the Danes retiring behind the Eyder. On the 15th of December, the Prince of Hesse, who commanded the Danish troops, proposed an armistice, which was agreed to by the Crown Prince. By the terms of this armistice, the whole of Holstein, and that part of Sleswick which borders on the Eyder, were to remain in possession of the allies; and the Danish army, which had taken refuge in Rendsburgh, was to be unmolested, but to receive provisions only through the country occupied by the allied troops, and not to add to or strengthen the fortifications of the place.

Renewal of hostilities, A. D. 1814.

The Danish government and the Crown Prince not being able to adjust the terms of peace, hostilities recommenced on the 5th of January, 1814. The first success of the allies consisted in the reduction of Gluckstadt; this was immediately followed by the advance of part of the Crown Princes' army, under the command of General Tettenborn, into Sleswick; and as the Danes were totally incapable of opposing any resistance, he soon overran the whole of Sleswick, and fixed his head quarters, on the 14th of January, at Colding, the frontier town of Jutland.

Peace concluded with Great Britain and Sweden.

The king of Denmark at last consented to the terms of peace proposed by the Crown Prince and great Britain; and accordingly, on the 14th of January, at Kiel, the British and Swedish minister signed treaties of peace with the plenipotentiary of the King of Denmark; the terms of which were, 1st, That Denmark should cede Norway to Sweden. 2d, That in return, Sweden should give up Swedish Pomerania to Denmark. 3d, That Stralsund should be a depot for British goods. 4th, That Great Britain should restore all she had conquered from Denmark, except Heligoland. 5th, That Denmark should join the allies with 10,000 men, on condition of receiving a subsidy of L.400,000 from Great Britain for the service of the year 1814. 6th, That the Danish government should abolish the slave trade. And, lastly, That Sweden and Great Britain should use their endeavours to bring about a peace between Denmark and the rest of the allied powers.

Part II. STATISTICS OF DENMARK.

CHAP. I.

General Geography.

Statistics. Extent.

The territories of the crown of Denmark are of great extent, and consist of several distinct, and formerly independent, principalities. Exclusive of the islands, they stretch from the river Elbe on the south, to the northern extremity of Europe and the shores of the Frozen Ocean, a length of 1400 English miles, by a medial breadth of 150. The dominions of the King of Denmark are as follow:—1st, *Denmark*, properly so called. 2d, The kingdom of *Norway*, including Danish Lapland. It is situated to the north of Denmark, and separated from it by the Categate. On the west and north it is bounded by the Northern Ocean, and on the east it is divided from Sweden by a ridge of barren mountains. 3d, *Iceland*, an island of great celebrity, and of considerable extent, in the Northern Sea, about 400 miles west from the coast of Norway. 4th, The *Faroe Isles*, lying south-west from Iceland, and about seventeen in number. 5th, *Greenland*. And, 6th, The colonies of Tranquebar, on the coast of Coromandel in India, and of Christiansburgh on the coast of Guinea, with the islands St Jan, St Thomas, and St Croix in the West Indies. A full description of the first of these divisions only, viz. Denmark, belongs to the present article. A more particular account of the others will be found under the articles Faroe, Greenland, Iceland, Lapland, Norway, &c.; and we trust our readers will be gratified to learn, that the articles Faroe and Iceland, have been written by Sir George Mackenzie, Bart. the most recent and intelligent traveller that has visited these islands; and the article Greenland, by Mr Giesecke, who resided there more than seven years, and who has been recently appointed Professor of Mineralogy to the Dublin Society.

Divisions.

Under the present article, we comprehend all the Danish dominions south of Norway, thus including the Duchies of Sleswick and Holstein. It is situated between the 53° and 58° of north latitude, and the 8° and 13° of east longitude, extending 260 miles in length, and 180 in breadth. It is bounded on the north by the entrance of the Baltic, on the west by the German Sea, on the south by the river Elbe and part of Germany, and is divided from Sweden on the east by that part of the Baltic called the Sound. This province, which, though by no means the largest, is, in a political view at least, by far the most important portion of the Danish monarchy; is composed of the Danish islands situated in the Baltic, and of the adjacent Peninsula, consisting of Jutland, and the Duchies of Sleswick and Holstein. 1st, The islands situated in the Baltic, which were the ancient and are also the present seats of Danish power, are, according to their extent and importance, as follow:—*Zealand*, which is the seat of government, and contains the capital of all the Danish dominions. It is of a circular form, and measures about 200 miles in circumference. The next in consideration is *Funen*, or *Fioma*, which is separated from Zealand on the west by the Great Belt, a strait of about 20 miles over. It is about 50 miles in length, and 40 in breadth. *Laaland*, a small but fertile island south of Zealand, 30 miles long, and 20 broad. *Langland*, to the west of Laaland, which takes its name from the figure of the island; its length being upwards of 30 miles, and its breadth scarcely eight. *Falstria*, or *Falster*, about 20 miles long, and 16 broad. *Bornholm*, the subject of frequent disputes between Sweden and Denmark, about 21 miles in length, and in breadth 13. To these may be added several others, as Mona, Samsoe, Arroe, Anholt, Lessaw, Amak, &c. 2d, *Jutland*, which is the name given to the most extensive and northern division of the Peninsula, formed by the German Sea and the Baltic. It is bounded on the south by Sleswick. It is about 180 miles in length by 98 in breadth. From north to south it is divided into the provinces of Aalburg, Wiburg, Aarhusen, and Ripen. 3d, *The Duchy of Sleswick*, or *South Jutland*, occupies the middle of the Peninsula, having Jutland on the north, and Holstein on the south. Its length is upwards of 60 miles, and its breadth 48 miles. 4th, *The Duchy of Holstein*, including within its limits Stormar, Dithmarsh, Wagerland, &c. has for its boundaries on the south, the river Elbe, the country of Lauenburg, and the territory of Hamburgh. This Duchy extends about 100 miles in length from east to west, and nearly as much from north to south.

Mountains.

While Norway abounds in lofty mountains, in Denmark there are no heights which deserve that name. The most considerable hills seldom rise above a few hundred feet, though, from the great extent of plain which they command, they are often very striking.

Rivers.

In Denmark, the rivulets are numerous, but, as might be expected from its circumscribed situation, there is scarcely a river of any note, or which is navigable for ships of burden, except the Eydar, which forms the boundary between Sleswick and Holstein, and after a course of about 50 miles falls into the German Sea at Frederickstadt. By means of this river and the canal of Kiel, a junction has been effected between the North Sea and the Baltic. Of this canal, a fuller description will be found under the head *Commerce*, in a subsequent part of this article. In Jutland is the river Gude, which has a course of about 40 miles, and falls into the Categate. In Sleswick, besides the Eydar already mentioned, are the Heveren, the Trenen, and the Hips, and also the Colding and Skodborg, which form the limits between this duchy and Holstein. In the duchy of Holstein, besides a share of the Elbe, there are the small rivers Haer and Trave, the former of which discharges itself into the Elbe at Gluckstadt, and the latter falls into the Baltic. Most of these rivers are navigable to a certain height for smaller vessels, and their mouths afford convenient harbours and anchorages.

Lakes.

The lakes of Denmark, though numerous, are none of them of any great extent. The lake of Ploen in Holstein, which is one of the largest, does not exceed ten miles in circumference.

Seas.

The seas of Denmark are the Northern or German Ocean, or, as it is called in Denmark, the Western Sea, and the Baltic, chiefly that part of it which is denominated the Categate. This sea is remarkable for the difficulties which it offers to navigation. It abounds in currents, and in sands, which often changing their situation, deceive the vigilance of the sailors. The storms too of the Categate are most violent, particularly towards the end of autumn, when vessels are exposed to the greatest dangers. In this sea, as in the whole of the Baltic, there are no tides, and its waters are less salt than those of the Ocean.

Straits. The straits formed by the Baltic, between the Danish islands, are numerous. The most remarkable of these are the two Belts and the Sound. The Little Belt, having Sleswick and Jutland on one side, and Funen on the other, at its greatest breadth between Arroe and Alsen, is about nine miles over. It is not more than one mile between Snohoe and Middelfart. The Great Belt divides the island of Funen from that of Zealand. Its breadth, at the usual passage between Nyborg and Kerser, is about eighteen miles; and at other places becomes still somewhat straiter. The Sound separates the island of Zealand from the Swedish province of Schonen. From Elsineur on the Danish to Helsenburgh on the Swedish coast, where it is narrowest, it is nearly four miles over. Through this strait, one of the most celebrated and most frequented in Europe, almost all ships bound to the Baltic pass. And it is here that the King of Denmark exacts from the merchant vessels of all nations, that toll which forms a considerable source of his revenue, and which is an acknowledgment of his sovereignty of those seas.

Gulfs. The Baltic also frequently advances into the country; and forms numerous gulfs, called in the language of the country *Fiords*. In Funen are the gulfs of Odensee, of Nyborg, and of Kiertmind. In Zealand is the gulf of Tsfiord, which divides itself into two arms, the one of which advances towards Holbeck, and the other towards Roschild. On the east coast of the Peninsula, the most considerable gulfs are those of Kiel and of Heiligenhafen in Holstein, and of Flensbourg and of Appenrad in Sleswick. To these may also be added the Sleye, in the neighbourhood of the town of Sleswick, which is more properly a long bay than a river. In Jutland are the gulfs of Colding, Veile, Horsens, Randers, and Marriager. These bays afford a number of good harbours, though sand, however, is apt to collect in them. Towards the north-east of Jutland is the great gulf of Limfiord, which penetrates so far into the country, that it approaches within two or three miles of the German Sea, while another arm of it advances southward to the town of Wiborg, a length of about eighty or ninety miles. At its entrance on the eastern coast it is about two miles broad, but afterwards becomes greatly wider. The towns situated on this gulf enjoy the advantage of being sea-ports, though in the heart of the province. But at the entrance of the Limfiord are considerable obstructions, and the depth of its waters has a good deal diminished. Perhaps it may one day become merely an inland lake. At not a more distant period than the commencement of the seventeenth century, it was practicable for ships of war to enter it, though now it will scarcely admit merchant vessels. These are the most important bays on the eastern side of the peninsula of Jutland. When we double Cape Skag, which is the most northern point of Jutland, and enter the Western Sea, the gulfs are less numerous and less considerable. The only gulfs useful for navigation, are those of Husum, Toendern, and Norstrand, in the Duchy of Sleswick. The navigation of the whole of this coast is greatly obstructed by continued shoals and sand banks.

Cities. Almost the only city of any considerable size or importance in Denmark is Copenhagen; though the Danes have dignified with this name above 60 of their towns. This is the capital of the kingdom, and the best built city of the north. It stands on the eastern shore of the island of Zealand, about 25 miles to the south of the Sound; and contains a population of about 90,000. The second city of Denmark is Altona on the Elbe, within a gun-shot of Hamburgh; and containing 25,000 inhabitants. In Zealand, besides Copenhagen, there are Roschild the ancient metropolis, Elsineur, Holbeck, &c. In Funen, Odensee the capital of the island, Nyborg, Sevenborg, and Alsens. In Jutland are Aalborg, Wiborg, Aarhusen, Ripen, Randers, Horsens, Fredericsodde, Colding, Ringkioping, &c. The chief towns of Sleswick are the capital Sleswick, Flensburgh the largest and most populous town of the Duchy, Gottorp, Ekrenford, Fredericstadt, Tonningen, Husum, Glucksburgh, Hadersleben, Tondern, Sunderburg, and Norburg. There are in Holstein, besides Altona already noticed, the towns of Rensburg, Kiel, Gluckstadt, Pinneberg, Itshoa, Wilster, &c. For a more particular description of the cities and towns of Denmark, see the separate articles ALTONA, COPENHAGEN, ROSCHILD, &c.

CHAP. II.

Face of the Country, Climate, Soil, Agriculture, Natural History.

Face of the country. THE aspect of the Danish islands is, in general, pleasant and cheerful, consisting of plains intersected by gentle hills, sometimes insulated, and sometimes continuous, forming agreeable vallies. The heights, for the most part, are clothed with pasture, or shaded by tufts of trees; whilst clear and azure lakes occasionally animate the scene. The province of Jutland presents a ruder aspect, but at the same time more varied and imposing, diversified with majestic forests, upland moors, and fertile pastures. Holstein and Sleswick are level and well cultivated countries, resembling England in their variety of hills, woods, rivulets, meadows, and corn fields. The environs of Ploen are distinguished for their picturesque, and those of Sleswick, Flensburg, and Apenrad, for their romantic beauties.

Climate. The whole of Denmark may be considered as possessing, in general, a humid and rather a temperate climate. The sky is often obscured with thick fogs. The west and south-west winds, which are the most frequent, generally bring rain. It falls in the greatest abundance during the months of October and November. According to a medium of twenty-six years, it rains annually about 130 days, and thunders thirteen. The transition from summer to winter, and from winter to summer, is very rapid; the agreeable seasons of spring and of autumn being but little known. Though the thermometer, in general, does not fall beyond 12° or 13° below freezing, nor rise to more than 25° above it, yet sometimes the heats in summer are very intense; and there are occasionally winters of extreme severity, and the seas are also frequently impeded with ice. The warm weather seldom commences before the end of May or the beginning of June, and the nights are cool during almost the whole summer. The cold sets in about the end of September, and it frequently freezes in October. The coldest months are December, January, and February; but during these there are often thaws for many days. In March and April the weather becomes milder, though it is subject to continual changes. A calm and serene sky, and an atmosphere free of vapours, are seldom enjoyed by the inhabitants of Denmark; but, in general, at least in the higher situations, the air is sufficiently salubrious. The heat is greater, and continues longer in the duchies than in the rest of Denmark. This is particularly the case in Holstein. The influence of the sun, joined to the quality of the soil, produces in some districts

Statistics.

of this province a luxuriance of vegetation, which reminds us of the fertile countries in the south of Germany; and sometimes the banks of the Elbe and the Trave exhibit the appearance of those of the Rhine, the Maine, and the Neckar.

Soil.

The soil of Denmark is no doubt diversified, but its prevailing character is the sandy, with a greater or smaller mixture of the others; a kind of soil which seems well suited to the humidity of the climate. It is by no means deficient in fertility, and well adapted both for corn and pasture. The soil of Zealand and Laaland is considered the strongest. It is more mixed, and admits of a more varied cultivation in Funen, Langland, and Falster. The soil on the eastern coast of Jutland is rich, and favourable to vegetation; and on the western coast there are extensive alluvions, which might be turned to advantage. Between the two coasts, a sandy ridge extends through the middle of the country, repugnant to cultivation, and producing only heath and some useless plants. At the northern extremity of this province, the coast is covered with a deep stratum of dry sand. It prevails particularly in the environs of the city of Skage, where a great extent of surface presents only the image of sterility. Similar collections of sand are to be met with, after turning the northern point of Jutland towards the west, and also on some parts of the coast of Zealand. These sands being raised in clouds by the wind, desolate the surrounding country, and overspread the cultivated fields. For the purpose of consolidating these sands, various kinds of trees and shrubs are planted, to destroy which is prohibited, under a severe penalty. They sow also in these places a plant called by botanists *elymus arenaria*, whose spreading roots bind the sand, while its large leaves break the force of the wind.

Whirlwinds of sand.

There was published, some years ago, a rescript of the king, for the purpose of directing the public attention to the most likely means of preventing the ravages of the whirlwind in the districts exposed to their scourge. Government, at the same time, circulated a memoir of Professor Wiborg, concerning the plants which grow in sand. In all the higher parts of Sleswick and Holstein, the soil is the same as in the other provinces of Denmark. But on the western coast, from the mouth of the Elbe nearly as far as the frontiers of Jutland, is a soil of a peculiar kind. That district, like a great part of Holland, owes its existence to the agency of the waters, and consists of alluvions, which, for ages, have been insensibly collecting. These depositions of the sea or of the rivers, which are extremely fertile, the industry of man has seized and converted into cultivated fields, a conquest without wars or treaties: But the preservation of this conquest requires the most active and persevering vigilance. The waters often attempt to recover their ancient dominion; and if they meet not with barriers capable of restraining them, they resume their rights, inundate the cultivated grounds, and in a few hours destroy the labours of many years. The most dreadful of these devastations happened in the year 1634. From the mouth of the Elbe to the town of Reben in Jutland, the relentless element carried every where destruction. Besides thousands of cattle and sheep which disappeared in this inundation, there perished above 1500 persons; and houses, mills, and whole villages were swallowed up.

Embankments.

The art of constructing banks has been brought to greater perfection since that disastrous period. They are formed of tough clay, about 19 feet high, and so broad that a carriage can easily pass along them. They are also provided with ditches, canals, and sluices, for containing the water necessary for the irrigation of the soil, and for carrying off what is superfluous. In Wilersmarch they use windmills for drawing the water into the canals. Often thirty or forty of these mills are to be seen in motion at the same time. Men of skill and experience in the construction of such works, who have lately examined the dikes, say, that notwithstanding the improvements that have been made, they are not yet sufficiently secure; and, indeed, it is not long since several districts have suffered by inundations. These works are the object of a special police, and overseers are appointed to see that they are kept in sufficient repair. The governors of the province, accompanied by skilful juries, visit them in spring and autumn. They impose fines on those proprietors who have been guilty of negligence; and such works as are improperly executed are begun anew, under the direction of experienced persons. An ordinance, published in 1800, prescribes an uniform mode of construction, and requires, that all plans of repair shall be submitted to the inspection of persons named by government for this purpose. In 1794 and 1795, the bank of Copenhagen advanced nearly a million of rix-dollars to different companies for the construction and improvement of these dikes.

Alluvions.

New alluvions are continually forming on this coast, which, when they have attained the requisite maturity, are inclosed by new dikes. Such a piece of ground is called *Kog*. As very considerable outlay is required for such undertakings, government grants a complete franchise to those who accomplish them. The remains of ancient embankments, frequently met with in the interior of the country, indicate these successive extensions of the land. Holstein and Sleswick are thus naturally divided into two different regions: the one consisting of those districts which have thus been reclaimed from the sea, and which occupy the western side of the peninsula; and the other comprehending the higher grounds on the eastern side. The former of these divisions is called Marschland, or the Marsches, and the latter Geestland. The superior stratum or soil of Marschland is composed of a rich fat earth, more or less mixed with sand; the second stratum is pure sand, sometimes mixed with gravel; and the last consists of a bluish coloured clay, which, being spread upon the surface, makes excellent manure. The whole of this part of the peninsula is one uniform plain, without any other elevations than the dikes. The sameness of the scene, however, disappears amidst the pleasure which the beholder derives from the general appearance of prosperity, the richness of the cultivation, and the triumph of man over an element the most formidable.

Diseases.

As might be expected from the humid climate of Denmark, and its low situation, surrounded on all sides by seas, and the frequent and sudden changes in the temperature of the atmosphere, those diseases which arise from obstructed perspiration, such as rheumatism, catarrh, &c. are prevalent. Cutaneous diseases were formerly very general, but they have now greatly decreased. In the lower districts of Sleswick and Holstein there often prevails a very obstinate disease, known by the name of the Fever of the *Marsches*. Upon the whole, the climate of Denmark is by no means unhealthy, and the inhabitants often live to a very advanced age.

Agriculture.

The agriculture of Denmark may be compared with that of Great Britain, which it very much resembles, and supplies the inhabitants with all the necessaries and

Statistics. Agriculture.

conveniences, if not with the luxuries of life; though the state of bondage in which the peasants are held, must be very unfavourable to agricultural enterprise and improvement. Since the middle of the last century, however, when considerable ameliorations took place in the condition of the labouring classes, and particularly within these last thirty years, agriculture, in all its branches, has been very sensibly improving, and has attracted much of the attention both of the public and of the government. In the year 1757, an economical society was projected at Copenhagen, and it commenced its labours in 1768. It was founded by individuals, but soon obtained the support of government. A donation of 3000 rixdollars was received on the part of the king, who has since annually contributed 1400. The members who, independently of correspondents, and of such foreigners as are fellows, have amounted, of late, to about 200, contribute each at least ten rixdollars yearly. The chief object of this society, is to promote improvements in agriculture, in the fisheries, and in the mines. A select committee holds once a year a public meeting, at which the prince royal presides, for the purpose of awarding prizes to useful memoirs, to industry, and to inventions. These prizes consist of honorary or of pecuniary rewards. From 1772 to 1792, the society distributed, in this way, 68,000 rixdollars to 4200 individuals. Count Otton-Thott and General Clasen have also founded prizes, to be decerned by the Copenhagen Society to the best works on general economy, and to the inventors of useful machines, either for agriculture or the manufactures; and General Clasen has bequeathed an estate, the rent of which is to be employed in the maintenance of an agricultural school. About this time, too, measures were adopted for the suppression of commons, which were very numerous in this country, and of very little advantage. The boundaries between the grounds belonging to the different villages and farms had been totally neglected, and the limits altogether unascertained, which occasioned not only innumerable disputes, but was also evidently a great drawback on improvements. The straighting and settling the boundaries of the different proprietors, have, therefore, been publicly recommended, and surveyors for making the necessary measurements distributed over the country, to the number of not less than forty. Government has also marked out to the proprietors of tythes a plan of reform on that subject, but has left the execution of it to their own patriotism and good sense. The greater part of the tythes of the clergy have already been commuted according to this plan, and it is probable that the others will be so also in the course of time. Servitudes also are diminishing, or becoming, at least, less burdensome, in consequence of agreements entered into between the proprietor and his vassals. The great proprietors. in order to enable the peasants the better to improve the soil, grant them hereditary leases. They have increased also the number of farms, by subdividing their estates; a practice, however, which, when pushed too far, is unfavourable to agriculture. The lands belonging to the crown, to cities, and to pious foundations, are very considerable. Of these a great part have been sold, and others are farmed according to the most approved principles. After this great alienation of the property of the crown, the king still possessed in the bailiwicks of Cronborg and Fredericborg some estates on the ancient footing. These estates have been measured and parcelled out into farms of nearly an equal extent. The servitudes and the tythes are suppressed or converted into obligations less burdensome. An annual sum of 30,000 rix dollars is expended on these farms in improvements of various kinds. The property of them is granted to the peasants on the sole condition of discharging the stipulated commutations. More than five hundred farmers have already been settled in this manner, and in the space of a few years their farms have tripled their value. Several private proprietors, emulating with a laudable zeal the example of their sovereigns, have given freedom to their peasants, released them from the burdens under which they laboured, and granted them every indulgence and encouragement. These public-spirited individuals have by these means, at the same time, promoted their own interest, and advanced the value of their estates much beyond those of their less patriotic neighbours. In the low district of the duchies of Holstein and Sleswick, the cultivator has always been free, and often the proprietor; and even in the higher lands, where bondage has long prevailed, many favourable circumstances have softened the yoke. There are here cultivators who, by their mode of farming, and particularly by their manner of cropping, give to their lands a productive power, from which they draw the greatest advantages. In 1786, there was formed, under the eye of government, an office denominated a *chest of credit*, the object of which was to furnish advances of money for the purpose of facilitating the agricultural improvements of the country. The original capital was about 750,000 rix dollars, consisting of property belonging to the crown, on the credit of which, the directors of the chest negociated money with the bank and private individuals. At first, this chest furnished advances at two per cent. in some cases, and in others at four. But since 1793, it has lent at four per cent. in all cases. Before granting these advances, information must be obtained concerning the nature of the undertaking, and the probability of reimbursement. The sum granted is furnished at intervals of six, twelve, or eighteen months, and sometimes of two years; and before any of the remaining portions can be obtained, satisfactory proof must be given that the former has been laid out according to its intended destination. The reimbursement is effected by a small annual payment in proportion to the loan, so as that the whole debt shall be liquidated in twenty-one, twenty-six, or twenty-eight years. This establishment, in the course of twelve years, has lent to the amount of three millions, and government has permitted them to raise their capital to five millions. One part of the sums advanced has been granted for the improvement of the soil and husbandry of the Isles of Jutland and of the duchies of Sleswick and Holstein. Another part has been set apart, as was already mentioned, for enabling the inhabitants of the low district of the duchies to preserve and complete the dikes, an object essentially necessary for the preservation of the land. And the peasants of Denmark have obtained sums, more or less considerable, for the acquirement of property, and for buying up their burdensome servitudes. Norway has always obtained a proportion of these advances for similar purposes. The direction of this institution is entrusted to men whose characters raise them above the suspicion of all personal considerations, and who are particularly enjoined to administer its funds with prudence and impartiality. These encouragements afforded by government, joined with the efforts of enlightened patriots, have diffused a taste for agriculture throughout all the Danish states.

Economical society of Copenhagen.

Chest of credit for agricultural improvements.

Statistics.

Vegetable productions.

The temperature of Denmark admits of the culture of all kinds of grain. It is the nature of the soil on which the choice depends. The island of Zealand yields the greatest quantity of barley and oats; that of Funen yields chiefly buck wheat. The isles of Laaland and Falster are best adapted for wheat. Jutland is well fitted for the culture of rye. Pease, beans, and lentils, are found in almost every part of the country. Forage is in general abundant, and the meadows have been much improved by the suppression of the commons. The duchies produce the principal kinds of grain in sufficient abundance for the support of the inhabitants, and also for exportation. The high grounds are most proper for the cultivation of rye, buck wheat, and oats. The sandy ridge, which pervades the whole length of both provinces, is fit only for oats or buck-wheat. The district of the Marsches present a picture of the most luxuriant cultivation. Wheat, barley, oats, pease, beans, thrive there most astonishingly. A considerable extent of soil is here allotted to the cultivation of rape. This plant, whose seed yields an oil much esteemed in Holland and in Germany, brings great profits to the cultivator. A part of the seed is prepared in the country, another part is exported without preparation. The refuse of the seed is good food for cattle; the stalks make good manure, and sometimes they are used for fuel. Sleswick alone, sends annually nearly 8000 tons of rape-seed to Holland. The potatoe, that most useful root, was at first despised in Denmark as in most other countries, but it is now more esteemed, and whole fields are appropriated to the cultivation of it. Common cabbage, and the different kinds of turnips and carrots, are very generally cultivated, and form a considerable portion of the ordinary food of the peasant. The isle of Amak, which has been called the garden of Copenhagen, furnishes that capital with an immense quantity of pulse and pot-herbs. This establishment owes its origin to the desire of Isabella the wife of Christian, of finding in Denmark the pulse and vegetables she had been accustomed to in the Low Countries. With this view, cultivators were brought from that country, and part of the Isle of Amak assigned to them, with numerous privileges, which their descendants still enjoy. Gardening has made considerable progress around the capital, and also in the provinces. Fruit trees are generally cultivated. Cherries, plumbs, pears, and apples, are often an abundant crop. In the low lands of Holstein, fruit trees thrive exceedingly. In Sleswick, the districts of Lundwit, and of the Isle of Alsen, are famous for the culture of apple-trees. Vessels often sail from the ports in the neighbourhood of their orchards laden entirely with apples, which they sell to great advantage in Norway and Russia. A single peasant will gain in this way the sum of 200 rix-dollars in one year. For encouraging the culture of fruit-trees, many proprietors, and in some instances government, have established extensive nurseries, from which they supply with trees the peasants and the other inhabitants of the country. Hops are cultivated to a considerable extent in Funen. The produce, however, is not sufficient for the consumpt of the country, which imports hops yearly to the value of 50,000 rix-dollars. There are some grounds appropriated to the cultivation of tobacco in the islands of Zealand and Falster; but this plant is chiefly cultivated in the environs of Fredericia in Jutland, by the French refugees invited thither by Frederic the Fourth. Under the reign of Christian the Fourth, the cultivation of flax and of hemp was recommended by royal authority. This recommendation has since been frequently renewed. But it is only very lately that the culture of these plants, which is of great importance in a maritime country, has been attended to by the generality of farmers. Nature produces, in many parts of Denmark, an useful plant, and which a small expence of labour would render more common, the herb manna, probably so called, because it is spontaneous, and because its seed is gathered in the morning before sun-rise. This plant, which delights in moist and marshy grounds, might be food for horses, while its seed, when ground, gives a meal of a good quality. Besides this, there are many other natural plants, of which the inhabitants might avail themselves more than they have hitherto done. In Sleswick and Holstein, hops, tobacco, flax, and hemp, have as yet been but little cultivated. For these several years past, in the district of Dithmarsh, the gathering of medicinal herbs, which grow there naturally, has furnished a lucrative source of traffic.

Animals.

The rearing of cattle is in Denmark an important object of rural economy, and has received a great degree of attention from government, who have founded at Copenhagen a public seminary and institution for the purpose of encouraging and promoting it. The horses of Denmark have been long known over Europe. Those of Jutland, and in particular of the district of Thyeland in the north of that province, are reckoned the strongest, but they are not so well shaped as those of Zealand and Funen. It is, however, in the duchies, and particularly Holstein, that we find that fine breed of beautiful steeds every where in such request. They are distinguished by their stately chest, their shape, their gait, their fire, and require better feeding than those of the other provinces of Denmark. From the bosom of their peaceful vales, these noble animals are conducted at great expence into foreign regions, to listen to the warlike trumpet, and carry the combatant through the ranks of the enemy; or to adorn the processions of the great, and drag in gilded chariots the illustrious favourites of fortune. The chief trade in these horses is carried on at Altona and Husum, from whence they are exported to Germany, Russia, Prussia, and France. Stallions from the king's stables, are distributed over the country for the accommodation of breeders; and those who rear the best horses are rewarded with prizes from the inspectors of studs appointed by government. In the year 1797, there was exported from Jutland and the isles 6000 horses, from Sleswick, 3647, and from Holstein 6386, which would bring into the country about 250,000 pounds sterling. The horned cattle of Denmark are also of a very excellent breed, and furnish an important article of exportation. The cows of the eastern coasts of the duchies, are of peculiar excellence, and particularly the large reddish coloured cows of the district of Eystersted, which, it is said, will give twenty-four cans of milk per day. For a long time the privilege of trading in cattle and of fattening them, was exclusively enjoyed by the great proprietors, by the farmers of the royal demesnes, and by the cities, to whom, according to fixed regulations, the peasants were obliged to bring the cattle reared on their pastures. Those only of a certain age and quality were allowed to be exported. Under all these restrictions and disadvantages, this branch of commerce was carried to a great extent. In 1788, government, however, suppressed the exclusive privilege of feeding and dealing in cattle, and all the burdensome enactments to which it had given rise. The export duties were lowered, and the expor-

Statistics.

tation of lean cattle, which was not before allowed, was also permitted. In 1774, the number of horned cattle throughout the whole of Denmark, was 640,211 cows, and 131,762 oxen.

In 1798, the exports from the isles and Jutland were 22,000 cattle, and 9000 tons of salted beef. In many districts are made immense quantities of butter and cheese, which are exported to different parts of Europe. Their dairies are placed on the same footing as those of Holland. The finest butter is that of Holstein; and connoisseurs esteem particularly the cheese of Eystersted in this duchy, and of Thyboe in Jutland. The rearing of sheep is another important branch of the rural economy of Denmark, and government has been at great pains to procure from other countries the best species, and those most suitable to the situation and climate, for the purpose of improving the native breed. It is in the low districts of Sleswick and Holstein, and particularly in the district of Eystersted, that the most valuable species is to be found. This breed is distinguished by the length, the fineness, and the whiteness of their wool. About 150,000 pounds of this wool is produced annually, of which 30,000 are used in the country, and the remainder is sent into the other provinces of Denmark, to Hamburgh, and to Holland. In the higher districts of the duchies, too, as well as in Jutland and the isles, great numbers of sheep are raised. Their wool, though it has not the superior qualities of that of Eystersted, of England, or of Spain, is, nevertheless, very valuable for the purposes of the country. The wool of the islands, excepting that of Zealand, is somewhat inferior. They sheer the sheep twice in the year. They are also in the habit of milking the ewes, for the purpose of making cheese. A Danish writer has computed the number of sheep in Jutland and the islands at 849,000. Goats, which are not allowed to be at large in Denmark, are scarcely to be found, except in the heaths of Jutland. Swine are raised in great numbers, and the farmer often derives considerable profits from these animals. The breed in the eastern parts of Jutland is small, and easily maintained. Those of the west are larger, and sometimes weigh eighteen stones. Besides supplying themselves, the inhabitants send annually about 10,000 cwt. of bacon to Norway, Holland, Hamburgh, and Lubeck. Great numbers of live hogs are also shipped on the Eyder and the Elbe. Poultry of all kinds form a profitable part of the produce of most farms, particularly geese and ducks, whose feathers are sold to great advantage for beds. The culture of bees, though formerly more extensive, is by no means neglected. In the islands of Funen, Falster, and Bornholm, the greatest quantity of honey is produced. The culture of bees is also very general in the peninsula; the schoolmasters in particular attend to it, and practise it very successfully.

Wild animals.

The immense forests, which formerly covered a great part of Denmark, abounded in wild animals. But in proportion as these forests have been cleared, and agriculture has improved, the more ravenous and destructive species have here, as every where else, almost entirely disappeared, and the others have greatly decreased. Boars are now no where to be found. The wolves are reduced to a very small number; but foxes are numerous, and hunting them a very common amusement. The hart and the deer are not scarce. Hares are plenty, and we sometimes meet with rabbits, though this animal does not appear to be a native of Denmark. The principal wild-fowl are the wild goose, the wild duck, the snipe, the swan, the moor-fowl, the woodcock, &c. This last is chiefly found in the woods of Jutland. Sea-fowl abound in the districts of the marshes, and on the small islands on the western coast of the peninsula. The island of Sylt furnishes annually nearly 40,000 wild ducks.

Fisheries.

The fisheries are of much more importance. It is said that the fishes were formerly more abundant in the Danish seas than they are now. The produce of these seas, however, is still sufficiently important, and might become yet more so were the fisheries under better regulations. The coasts of Zealand, of Funen, and of the other islands, furnish productive fisheries. In these seas the mackerel and whiting abound. Of all the waters which wash the Danish coasts, those of Limfiord, with its numerous arms, seem best adapted for this purpose. Here they fish chiefly herrings and eels. In the neighbourhood of Skag and Fladstrand, as well as on the whole coast of Wensyssel, they take the best fish, flounders, and cod. The gulfs of Mariager and Randers are full of fish, and afford excellent salmon. In the gulf of Veyle are found several kinds of flat fish, herrings, and small cod. In all these gulfs the sea is so little salt, that fresh water fishes thrive in them. The carp of Limfiord are not, however, so good as those of the ponds. On the western coast of Jutland, the greater part of the inhabitants are employed in the fisheries. The salmon, the bretfish, the flounder, and the cod, are the principal species found in those parts. According to the registers of the custom-house of Aalburg, this city exported yearly from 1720 to 1730 above 23,109 tons of salted herrings, but from 1754 to 1765 their exportation amounted only to 8298 tons. The Swedes, who had hitherto been supplied with herrings by the Danes, now began to rival them in this branch of industry. The want of credit diminished the fisheries of Limfiord; and at present the greater part of the herring taken on the coast of Jutland are consumed in the Danish states. The white fish are dried and salted, and either sold in the country, or sent to Lubeck, the merchants of which place forward them to Italy and Poland. In the river or bay of Slie and the gulf of Flensburg, are taken a small species of herring of excellent quality. This fishery, which was famous several centuries ago, still exists. The herrings make their appearance in March, April, and May; they are found also in autumn, but in small numbers. The proprietors whose lands lie along the Slie, to whom the fisheries belong, farm them out. Besides what are consumed in the country, they export annually of the herrings taken here, nearly 1000 tons to Germany and Copenhagen. The fishery of the small cod called *aigrefin*, below the island of Heligoland, employs about three hundred individuals, and a number of vessels of particular construction. The inhabitants of the village of Blankensen, and of some other places on the lordship of Pinneberg, employ about 150 vessels in the neighbouring fisheries. The produce, which is valued at 100,000 dollars yearly, is carried chiefly to Altona, Hamburgh, and Holland. In 1767, there was established at Altona a North sea herring company. The grant was for ten years; but before the expiration of that term, the king bought up the deeds, and the fishery has since been carried on, on his account. In both the fishery and the preparation of the herring, they imitate, as nearly as possible, the practice of the Dutch. The produce amounts to 6000 tons yearly, a considerable part of which goes to Hamburgh, to St Petersburgh, and even to Hungary. The coasts of Jutland possess oyster-banks, rich enough to afford a considerable supply for exportation. Among the islands situated along the western coast of Sleswick, are found

Statistics.

oyster-banks still more valuable, which belong to the crown, and the formation of which is ascribed to Canute the Great. These banks are sometimes half a mile in length, and 14 feet under the water. The produce of this fishery, which is let to a merchant of Toendern for 75,000 dollars payable per advance, is sold in the provinces of Denmark and the North of Germany. The superior quality of these oysters is ascribed to the fresh waters, which, in spring, are let into the sea through the sluices and the canals. The lakes, the rivers, and ponds, contain pike, perches, carp, eels, and cray-fish. The fisheries of Gessenfield owe their origin to Peter Oxen, who brought the first carp from France in the end of the sixteenth century, and recommended the propagation of this fish in the fresh waters of Denmark. Most of the large estates, particularly in Holstein, have ponds, some of which will produce 800 rix dollars per annum. Many of these fisheries also belong to the king, some of which are let, and others managed on his account. All these fresh water fisheries might be improved and rendered of much greater value.

Minerals.

Although Denmark contains none of the primitive or transition rocks, and but few of the flætz series, and is almost entirely destitute of the more beautiful and striking minerals, still its mineralogy is by no means uninteresting.

The basis or fundamental rock of Jutland, Sleswick, Holstein, Zealand, Laland, Falster, &c. appears to be sandstone; on it rests chalk, which varies in hardness, contains flint, and also numerous petrifactions: the chalk is covered with, or contains beds of gypsum, which sometimes forms considerable eminences, as at Segeberg, near Kiel. These are all the flætz rocks hitherto observed in Denmark, (with the exception of Bornholm, afterwards to be mentioned). They occur but seldom at the surface, owing to the universal and frequent deep cover of alluvial strata. The most striking sections are on the sea coast; and of these the most remarkable is that of Stevensklint, in Zealand. Immediately over the chalk rests a remarkable bed of marl, from a few feet to upwards of seventy feet thick: it contains fragments of chalk, and abundance of loose masses of flint. It is covered with a bed of loam, and there is observed an uninterrupted transition from the loam into the subjacent marl; and both of these beds appear to have been formed from the chalk. Superimposed on the loam is a vast bed of sand, which is sometimes in the state of blowing sand, and is then very destructive to the labours of man, or is more or less aggregated together by means of clay or marl, so as to form a kind of sandstone. In some places we observe beds of this sandstone alternating with a peat, which is uncommonly like coal. The sand is covered or intermixed with boulders, or rolled stones of different kinds, as of granite, gneiss, sienite, porphyry, &c. which, from their nature and their connection with the subjacent alluvial matters, appear to have been transported from the mountains and hills of Scandinavia and Germany, by that commotion of the water which opened a communication between the Baltic and the North Sea. This sand is more or less extensively and deeply covered with peat, which is the principal fuel of these countries; and sometimes the peat is associated with bog-iron ore.

The minerals of Denmark, in an economical point of view, are not of very great importance. Coal, that most useful mineral, occurs but in small quantity, and, as far as we know, only in the island of Bornholm. Peat, as we have already remarked, is the principal kind of fuel; and some varieties of it are so bituminous, that the peasants make use of it instead of candle. Amber is found, along with brown coal, in the island of Bornholm; also floating on the coasts of Zealand, and other islands in the Baltic. The island of Bornholm also furnishes good porcelain earth, excellent building stones, and also small but beautiful transparent rock crystals, which are situated in a variety of marl; and a kind of limestone, which is considered as of the nature of marble. Near Kiel, in Holstein, there are gypsum quarries, which have been worked for a long series of years. Those of Segeberg, which belong to the king, employ about seventy individuals, and from 1773 to 1793 yielded a profit of 1,192,351 dollars. The salt springs in the neighbourhood of Oldesloe have been known since the twelfth century. The water is raised by means of mills and pumps into the buildings prepared to receive it, and the process is the same as takes place in other salt works of the same nature. The number of workmen employed is about forty; and the quantity of salt produced is 18,000 tons annually, which is more than sufficient for the consumption of the country. The inhabitants of Jutland procure a small quantity of salt from sea-weed, after burning it to ashes.

Forests.

The extensive forests which at one period covered almost the whole of Denmark, as was mentioned already, have now generally disappeared. In some districts of Zealand and Funen there is a considerable quantity of wood, and in Jutland there are still some large forests. We also meet with extensive forests in Sleswick, in the district bordering on the Baltic. The trees in these forests are chiefly the oak, the beech, and the ash. The city of Itzhoe in Holstein exports wood to Hamburgh and Holland; and the burgh of Elmshorn in the same province carries on a lucrative trade in charcoal.

CHAP. III.

Manufactures.

Manufactures.

The manufactures of Denmark are neither many, nor very important. Government has made frequent attempts to extend them; but by aiming rather at the introduction of foreign manufactures, than at the encouragement of those suited to the country, and also by interfering too much with individual enterprise, their well meant endeavours have not been crowned with all the success that was expected. It is evident, from the constitution of the Danish corporations, that the knowledge of the mechanical arts, and almost all the different trades, have been introduced into this country, or at least brought to perfection, by Germans. Indeed, the greater part of the tradesmen employed in all the northern states, came originally from Lubeck, Hamburgh, Bremen, and the adjacent countries; and we still meet with great numbers of these German artizans in Copenhagen, and in many of the other Danish cities. The native tradesmen, though they exact high wages, work but slowly, and have very little taste. Their education is much neglected; but an institution was founded at Copenhagen in 1798, for the instruction of young mechanics, which may be attended with considerable advantage. The vassalage of the peasants, who can exercise no trade but by the permission of their lords, and the corporation monopolies, have been unfavourable to the increase and prosperity of the manufacturing and mechanical arts; but several late enactments have very considerably diminished the evils of these systems. It is in Copenhagen that the greatest encouragement has been given to manufactures, and the chief manufactories of Denmark are in this city and its environs. Some cities in Holstein and Sleswick are declared free; and the effect of this on their prosperi-

Statistics.

ty, particularly on that of Altona and Christiansfeld, is very sensible. It is in these two cities that the most skilful artizans are to be found.

Woollen cloths.

The manufacture of woollen cloths is one of the most considerable, and is very suitable to a country in which this article forms an essential part of dress, and which is so well adapted for the rearing of sheep. Denmark has furnished, for many centuries, wool for the coarse cloth which the peasant wears, and which he frequently manufactures himself. But besides what the district of Eystersted furnishes, they import for finer cloths a considerable quantity from Poland, Spain, and Mecklenburgh. The number of hands employed in the woollen manufactories in Copenhagen, in the islands, and in Jutland, is not less than eighteen hundred. The value of the original materials may be about 97,000 rix-dollars, and that of the articles when manufactured 165,000. They manufacture also shalloons, camlets, and cassimires, for which purposes they use chiefly the wool of Eystersted. The produce of these manufactures is reckoned at 94,000 rix-dollars, and the original materials at 41,000. The great manufactory of woollen cloth for the use of the army, was established at Copenhagen in the reign of Frederic the Fourth. It employs about 1200 hands, and delivers yearly between a hundred and forty and a hundred and fifty thousand ells.

Hosiery.

About 70 looms are employed in the capital in the manufacture of stockings, nightcaps, mittens, and other articles of woollen hosiery, to the annual amount of about 27,000 rix-dollars. There are similar manufactures at several other places. The peasants of Jutland furnish a considerable quantity of stockings. The single community of Hoeringsholm has sold in one year 20,000 pairs. Father, mother, children, servants, are all busily employed during the winter evenings, some carding, some spinning, and others knitting or working on the loom. The produce of this commendable industry yields yearly not less than sixteen thousand dollars. It is carried to Copenhagen, from whence it finds its way into the provinces, and sometimes into foreign countries.

Manchester cloths.

There has been established at the gates of Copenhagen a manufactory of Manchester cloths. It was erected according to the English fashion, by a Swede of the name of Norberg, for the behoof of the king, but it has since been sold to individuals. This extensive establishment is well conducted, and gives support to about two hundred people. They manufacture both cloths, entirely cotton and also mixed. They sell annually to the value of from twenty to thirty thousand dollars. There has sometime ago been erected another manufactory of the same kind, in the bailiwick of Hirseholm, a few miles from Copenhagen. In that place cotton stockings are manufactured, but in small quantities, the annual value not being above two or three thousand dollars.

Calicoe printing.

For a long time, one particular establishment enjoyed, on advantageous terms, the exclusive privilege of printing calicoes. But this branch of manufacture has been free since the year 1754. Besides seven large manufactories of this kind, employing about 360 persons, there are several smaller ones. Altogether they print yearly goods to the value of about 366,000 rix dollars.

Linens.

The manufacture of linens, &c. will not flourish, it is probable, until the country itself produces a greater quantity of the materials. The annual importation of flax and hemp into Norway and Denmark, amounts to the value of 460,000 rix dollars. There are four manufactories of linen cloth in this country, one in Zealand, one in Funen, and two in Jutland. These employ about fifty-five looms, and make about 25,000 ells of cloth of different qualities, yearly. In the villages throughout the country a considerable quantity of linen is manufactured, both for domestic consumption and also for trade. That of Jutland is of the best quality. The town of Aalborg has sometimes exported in the course of a year about 60,000 dollars worth of linen, manufactured by the Jutland peasants. Denmark does not, however, furnish linen cloth sufficient for the consumption of the country, but obtains a very considerable supply from abroad.

Sail cloth.

There is only one manufacture of sail-cloth deserving to be mentioned. It furnishes employment to about 400 persons, and yields a produce worth about 18,000 dollars. The rest of this article is brought from Russia.

Cordage.

There are rope-yards at Copenhagen, Elsineur, and several other places. But great quantities of cordage are yearly imported, and chiefly from Russia.

Silk.

The silk manufactures, say the Danish writers, have cost the public not less than 200,000 dollars in prizes and other encouragements of various kinds. The result of these efforts has not, however, answered expectation. The number of looms employed at present in the manufacture of silk-stuffs, may be from 140 to 150. In 1789, there were six ribbon manufacturies, employing about 40 looms, and 313 workmen. The annual produce was about 32,175 rix dollars.

Gauzes.

In the same year, there was about 38 looms for gauzes, employing about sixty-seven hands, and producing about 17,400 dollars. The annual produce of the manufacture of silk-stockings will amount to 13,000 rix dollars.

Paper.

Denmark has long paid a considerable tribute to foreigners for the different kinds of paper. About 1759, this article cost them at an average 15,000 rix-dollars yearly; and in 1793, upwards of 100,000. One of the greatest obstacles to the establishment of paper manufactories, is the difficulty of procuring rags. Various measures have been resorted to for removing this obstacle, which it is hoped will in time succeed. The paper manufactory at Joegersborg furnishes yearly about 15,000 dollars worth of paper. That at Roschild is quite inconsiderable. An extensive paper manufactory was erected some years ago, but the great supply is still derived from abroad. Copenhagen has a good manufactory of paper for household furniture. It has likewise two manufactories of cards, which furnish Denmark, Norway, and the duchies, with 144,000 packs yearly, all of which must be stamped.

Leather.

For the encouragement of tanneries, the exportation of raw-hides was prohibited in 1746. These manufactories have, indeed, since that time, increased, but have never yet been able to supply the wants of the country. There is one leather manufactory in Copenhagen, and another about two miles from the capital, of which the annual sale amounts to between thirty and forty thousand dollars.

Gloves.

The city of Randers, in Jutland, has been long famous for the manufacture of dog skin gloves, but they are now reduced to a very small number; and this manufacture has been, for some time past, chiefly carried on at Odensee in Funen, where they also make saddles and harness, that are much in request.

Refining of sugar.

Since the acquisition of the American islands, the refining of sugar has formed one of the manufactures of Denmark. The company which, in 1734, obtained the exclusive privilege of trading to these islands, procured also the sole right of refining sugar, and of supplying with this article the Danish states. But in 1754, this monopoly was abolished. There were, in 1793, seven sugar houses in Copenhagen, containing in all 68 boilers; but in general the third or fourth part of these boilers were not at work. These sugar-houses employ 340 workmen, and refine 13,770,000 pounds of sugar yearly. Besides the sugar-

Statistics.

houses of the capital, there are two at Elsineur which manufacture 800,000 pounds of the raw material; one at Odensee, which manufactures 700,000; and two at Alborg, which manufacture 300,000. The distillation of spirits from grain is an important branch of manufacture in all the countries of the north. In Denmark there are many distilleries, but those of Copenhagen have long been the most considerable. The distillers, in number three hundred and sixteen, form a corporate body, enjoying some peculiar privileges. In 1800, the distilleries consumed 287,824 tons of grain, which yielded 2,347,850 gallons of spirits. The first soap-houses in Denmark were established in 1662, at Copenhagen. There are now six or seven in this city. There are soap-houses also at Aalborg, and in some other places. The total produce of these manufactories is valued at 72,000 rix-dollars; and the original materials, which are brought from abroad, cost about 32,000. The inhabitants of the village of Worup, in the canton of Worde, and of many other places in Jutland, have, for a long period of time, manufactured a species of black pottery, remarkable for its solidity and its lustre, and much in request, not only in Denmark, but also in Hamburgh and Holland. The earth which they employ for the purpose, is a fine bluish clay found in the neighbourhood, to which they add a mixture of sand, carefully cleaned. This branch of industry produces, within three parishes, nearly 13,660 rix-dollars yearly. There are manufactures of earthen ware also in the isles of Bornholm and Falster. At the village of Castrup, in the isle of Amak, is a manufactory of delft-ware, which sells readily in Copenhagen. In 1774, a manufacture of porcelain was established at Copenhagen by public subscription, under the direction of Francis Henry Muller, a man of great chemical knowledge. But the profits of this manufactory, which the king was at last obliged to purchase to prevent the ruin of the individuals concerned, have never yet covered the expences of the establishment. To encourage this manufactory, the importation of foreign porcelain is prohibited, with the exception of what is brought from China by the ships of the Asiatic company. At Fredeickswaeerk, there is an extensive manufactory of brass cannon, mortars, bombs, balls, and powder, for the use of the army and navy. From 1762 to 1772, this manufactory delivered nine hundred pieces of cannon and mortars, twenty thousand bombs and grenades, and 3,000,000 pounds of powder. In 1802, the number of workmen employed in this manufactory was 920. Another manufactory, situated in the neighbourhood of Elsineur, furnishes annually 3500 muskets, and a great quantity of bayonets, pistols, and sabre blades, and gives employment to 400 people. In Copenhagen there is a manufactory of nails, &c. belonging to a company of merchants. There has also been established in the same city, another manufactory of ironmongery goods, by an individual. Two miles from Copenhagen, on the banks of a small stream, are three brass foundries. In these there are generally 300 workmen employed; and the annual consumption of brass, when the sale is good, is about 94 tons. There has been a foundery of printers types in Copenhagen since the year 1740, which supplies the printers of the country, and sometimes makes exportations to Sweden and Russia. There are various other manufactories in Denmark, which are either too inconsiderable to merit particular description, or of which the extent and importance have not been sufficiently ascertained; such as the manufactories of sealing-wax, of hair-powder, and of starch; as also those of tiles, of bricks, of tobacco, of tobacco-pipes, of hats, and candles, &c. In the duchies of Sleswick and Holstein, which are chiefly agricultural countries, the manufactures have not been carried to any very great extent. These provinces are not, however, altogether destitute of them. There are manufactures of woollen cloth, of carpets, and of bedcovers, at Husum in Sleswick, and at Altona, Neumunster, and Rendsburg in Holstein. Altona and Vansbeck have considerable establishments for the printing of calicoes, in which they carry on a trade. The paper manufactories of Flensburg, and of some other towns; the tanneries of Altona; the glass works of the same city, and its tobacco manufactures, also deserve to be noticed. The distilleries of spirits from grain, at Flensburg, are two hundred in number, which send their produce chiefly to Norway. The distilleries at the same time fatten cattle with the refuse of the grain, which they likewise export. This branch of trade altogether circulates 200,000 rix-dollars yearly. Around the gulf of Flensburg, are a great number of tile-works, the produce of which is sold to advantage in Copenhagen. The Hernhutes, the founders of Christiansfeld, and its only inhabitants, have introduced into it all kinds of manufactures, which are in a flourishing state. Besides the artisans, whose goods are in great demand, this city contains manufactories of woollen cloth, of woollen hosiery, of candles, of soap, and of sealing-wax, as also distilleries and breweries. The manufactures of this place, though high priced, obtain a ready sale.

Distilleries. Soap. Pottery. Porcelain. Ordnance. Fire arms. Iron goods. Brass foundries.

CHAP. IV.

Commerce.

Internal commerce.

No country can be better adapted for internal commerce than Denmark. The seas with which it is encircled and intersected, and its numerous gulfs which often penetrate into the very heart of the country, and sometimes extend nearly from one sea to another, afford the utmost facility of communication between the different provinces. These natural facilities of interior navigation which the inhabitants of Denmark possess, are considerably lessened, however, by their neglecting to clear the entrances into the harbours, which are in general much obstructed with the sand and mud that has been allowed to collect for a great period of time. Denmark is by no means distinguished by the same facility of intercourse by land. The roads long continued in the most deplorable condition, and occasioned much surprise and inconvenience to travellers. The public attention was at length directed to this subject, and in 1778, a plan for the general improvement of the roads throughout this country was adopted, and each proprietor assessed in an annual portion of labour or of money for this purpose. This plan has been gradually executing, and there are now some roads in Denmark, particularly that from Elsineur by Copenhagen to Corsær on the shores of the Great Belt, equal to those of any other country. The principal internal traffic of Denmark is carried on in the markets and fairs, which are held in the different cities, at which the manufactures and commodities of the place, and the productions of the neighbouring country, are exposed to sale. With the exception of Copenhagen, Odensee, Aalborg, Ripera, Fredericia, and Aarhuus, most of the cities of the islands and of Jutland are in a very languishing condition. A short and easy communication has been effected between the city of Odensee and the sea, by means of a canal, which cost about 75,000 dollars. Several navigable rivers, the Elbe, the Trave, the Stoer, and the Eyder, facilitate the interior communication of the duchies.

Roads.

Statistics.

Altona, Flensburgh, Kiel, Husum, Christiansfeld, and Tœndern, have the principal share of the commerce of these provinces. There is held annually, in the month of January, a great fair in the town of Kiel, during which time this place is the rendezvous of all that is rich and valuable in the two duchies. The canal of Kiel, which unites, as was mentioned above, the Baltic with the river Eyder, which falls into the German Sea, forms the great inland navigation of Denmark. This important work was begun in 1777, and finished in 1784, and cost nearly 800,000 pounds sterling. Its length is about 22 British miles and a half. Its breadth is 100 feet at the top, and 54 at the bottom, and its smallest depth 10. It admits vessels of 120 tons burden. The vessels from Kiel must be drawn by horses as far as Rendsburgh. From Rendsburgh to the sea, they use sails. The whole length of the navigation from Kiel to Tonningen, or from the Baltic to the ocean, is about 105 miles. Since the opening of this navigation, the passage round Jutland, always long, and often dangerous, has been mostly abandoned. This canal has greatly advanced the trade and prosperity of Sleswick and Holstein, and facilitated the intercourse between all the Danish states. It has also been the means of forming new and lucrative connections with foreigners, who, in many cases, prefer the passage through the canal to the ancient navigation; though every vessel passing this way, is of course subjected to the payment of a toll. The following Table will give the reader an idea of the navigation of the Kiel or Holstein canal.

Inland navigation.

Table of the Vessels which have passed through the Holstein Canal between the years 1784 *and* 1798.

Years.	Danish vessels.	Foreign vessels.	Total.	Years.	Danish vessels.	Foreign vessels.	Total.
1784	...	...	77	1792	787	722	1509
1785	409	44	453	1793	849	1441	2290
1786	333	67	400	1794	927	1192	2019
1787	520	125	645	1795	983	970	1953
1788	490	136	626	1796	921	1258	2179
1789	792	280	1072	1797	925	1180	2105
1790	678	293	961	1798	1086	1164	2250
1791	794	456	1250				

The facility of communication which is thus afforded between Denmark, Norway, and the duchies, is of the greater importance, as those provinces have various articles to interchange with each other. Copenhagen sends to Holstein the American and Indian produce, and receives in return German goods. For a long time past, a packet-boat has sailed between Kiel and the capital. Norway procures from Denmark and the duchies, corn, spirituous liquors, and several kinds of manufactures, and in return furnishes these provinces with iron, copper, fish, and oil. Denmark and Norway can exchange almost all kinds of commodities without any duty. The duchies can import their produce free of duty into either of those provinces, but their manufactures must pay a rate of entry. The trade to Finmark or Danish Lapland, which belonged at first to an exclusive company, and afterwards to the king, has, since the year 1787, been open to all the subjects of the Danish states without distinction. They carry thither corn, spirits, tobacco, cloths, and utensils of various kinds, and bring back fish, oil, rein-deer skins, furs, &c. In 1788, the imports at Copenhagen from Finmark amounted to 42,376 rix-dollars. The trade to Iceland too, was long in the hands of successive companies of Danish merchants, who ruined the province to enrich themselves. In 1789, a free trade with this island also was allowed to all the inhabitants of the Danish states, but foreigners are still entirely excluded. The imports from Iceland, which consist of dried and salted fish, oil, salted beef and mutton, tallow, hides, feathers, eider-down, sulphur, wool, stockings, mittens, &c. amount annually to 200,000 rix dollars. And the commodities sent to that province amount to about 150,000, consisting chiefly of meal, beer, spirituous liquors, wine, woollen and linen cloths, hats, coffee, tea, spices, salt, ironmongery, paper, and soap. Since 1787, Bergen, Christiansand, Altona, and some other places, have shared with the capital the profits of the trade to Iceland. A packet-boat sails in spring from Copenhagen to Iceland, and returns in autumn to Christiansand in Norway.

Commerce with Finmark.

With Iceland.

Denmark imports from the Faroe islands, the trade of which has never yet been declared free, dried and salted fish, oil, feathers, hides, tallow, and woollen stockings, and it sends thither meal, spirituous liquors, tea, coffee, sugar, spices, linen, glass, and several other articles. The exports to these islands amount, at an average, to 22,251 dollars yearly, and the imports to nearly the same sum.

With the Faroe isles.

Denmark sends out a considerable number of vessels to the whale fisheries of Greenland. It imports besides from the settlement, oil, fish, eider-down, and furs, and sends out meal, coarse woollen cloths, tobacco, spirituous liquors, sugar, and spices. The exports to Greenland will amount to about 80,000 dollars yearly, and the imports, including the produce of the whale fisheries, which is fully the half, to about 180,000.

With Greenland.

The commerce of Denmark, with its islands in America, like that, with its other distant possessions, was long carried on by oppressive monopolies. Before the late war with Britain (Feb. 1814.) suspended this branch of their commerce, by depriving them of their islands, the trade to St John and St Thomas had, however, become free to all the subjects of Denmark. Vessels were likewise sent from all the Danish ports to the island of St Croix; but the cargoes they brought home were to be delivered at Copenhagen, unless the ships belonged to some of those cities in which sugar houses had been established. The cargoes destined for these possessions, consisted of laces of all kinds, of iron and of copper, of Danish and foreign manufactures, and of Indian commodities. Sugar, rum, and cotton, were the principal returns of the Danish islands; but indigo, tobacco, mahogany, and coffee, were also procured from other places in those parts, through the medium of these colonies. The number of ships employed in this branch of Danish commerce varied according to circumstances; but they may have amounted at an average to between 70 and 80, of from 80 to 120 tons burden. The Danes carried on a small trade also in one or two ships, with their settlements on the coast of Guinea. They sent out brandy, linen, Indian commodities, gun-powder, and arms, and brought home elephants teeth, and gold.

With the American islands.

The slave trade was long with the Danes, as with the other commercial states of Europe, the principal branch of commerce on the coast of Africa. But this horrid traffic ceased in 1803, agreeable to an edict published in 1792; and let it be recorded to the honour of the Danish government, that arbitrary though it be, in this instance it first recognised the sacred rights of humanity, and led the way in those efforts which the present age is making, to wipe away the disgrace of the civilised world.

Slave trade.

In 1616, a Danish East India company was established by Christian the Fourth. This, as also two other successive companies, have been dissolved. The present East India or Asiatic company was established in 1732, with the exclusive right of trading to all places

East India companies.

Statistics.

between the Cape of Good Hope and China for forty years. They also obtained the government of the Danish possessions in India, and the right of making treaties in their own name with the Asiatic princes. When their charter expired in 1772, it was renewed for twenty years, but with considerable alterations. The commerce with China was again bestowed exclusively on the company, but that with India was opened to individuals on certain conditions. In 1792, the company obtained a second renewal of their charter for other twenty years, on nearly the same terms as the former; but the freedom of the Indian trade was then still further extended. Vessels may now be freighted by private adventurers, not only in all the Danish, but also in foreign ports, on obtaining the necessary licences. Their cargoes on their return, must, however, be brought to Copenhagen, and sold by auction. The number of these private vessels were, in 1797, eleven, of which three were from Danish, and eight from foreign ports. In 1798, there were thirteen, four Danish, and the rest foreign. In 1799, they were the same as in the preceding year. The capital of the Danish East India company is 2,400,000 rix dollars, divided into 4800 shares of 500 rix dollars each. During the American war these shares sold at 1800 and 1900 rix-dollars, and the dividends were as high as cent. per cent. From the establishment of the company in 1732 to 1745, the value of the cargoes sent from Copenhagen for the Indian commerce, amounted altogether to 3,973,474 rix dollars, and the value of the returns to 7,470,761. From 1781 to 1787, the exports amounted to 7,559,444 rix dollars, and the sale of the returns brought at Copenhagen, after deducting the duties, 12,775,872. From 1780 to 1793, the profits of the Indian and Chinese commerce amounted to 6,308,198 rix dollars. Tea, rhubarb, and porcelain, are the principal articles brought from China. The establishments in India furnish calicoes, silks, sugar, rice, pepper, ginger, cinnamon, indigo, opium, arrack, and saffron. Besides the silver for China, Denmark ships for the Indian market, metals, spirituous liquors, pitch, and various manufactures. The vessels employed in the Indian trade are of four hundred, and those in the Chinese of a thousand tons burden.

Trade with India and China.

Foreign commerce.

The foreign trade of Denmark was long in the possession of the Hanse towns, and particularly of Lubeck; but the kings of Denmark wishing to shake themselves free of the Lubeckers, who often interfered in the politics of the North, encouraged commercial intercourse with the Dutch, who reaped the chief advantages of the Danish foreign trade from the middle of the sixteenth to the end of the seventeenth century. About that time the Danes began to desire a commercial marine of their own, which they by degrees acquired; and which, during the almost constant neutrality they have maintained since the peace of 1720, has been vastly increased. The importation of all foreign commodities into Denmark is permitted on paying the stated duties, with the exception of the following articles: Sugar, either raw or refined, coming from European ports; porcelain, coloured delf, cards, burnt coffee, printed calicoes, and a few kinds of woollen cloth. Some articles of necessity, and such as are essential to the encouragement of the arts, are exempted from the rates of entry. The exportation, also, of all sorts of commodities is permitted from the Danish states, on paying the duties, with the single exception of the wood of certain districts in Norway. The merchants of Denmark have formed relations with most of the commercial states. They frequent the ports of the Baltic, particularly St Petersburg, Riga, and Memel, with herring, dried fish, the woollen manufactures of Iceland and the Faroe islands, salt from France, Spain, and Portugal, the commodities of India and China, oysters, and dog-skin gloves. And they bring home potashes, planks, firewood, hemp, flax, cordage, iron, copper, and linen. The commerce with Germany is important. The Germans draw from this country a great number of horses, cattle fattened in the pastures of Marscheland, butter, cheese, fish, oil, woollen stockings, sugar, and tea; and give in exchange, thread, linen, wool, brandy, wines, ironmongery, paper, and books. The inhabitants of Sleswick, Holstein, and Norway, have long maintained an intimate commercial intercourse with the Dutch, from whom there is a great demand for rapeseed, wood, fish, &c.; and who give in return spices, medicines, seeds, tobacco-pipes, and paper. The commerce of England with the Danish states is chiefly with Norway, whence it imports a great quantity of wood. Most of the commercial towns of France are well acquainted with the Danish flag. The articles of exchange are, on the one side, butter, cheese, horses, fish, wood, and various Russian commodities; and, on the other, salt, wines, fruits, brandy, silk and woollen stuffs, and paper. Denmark exports for Spain and Portugal much the same articles as for France; and receives in return, salt, wines, dried fruits, and American goods. The Danish commerce in the Mediterranean, including the ports of France and Spain situated on that sea, employs a great number of ships. These vessels are laden outward with wood and fish from Norway, beef and butter from Holstein, and iron from Sweden; and they bring home wines, brandy, fruits, oils, and salt. The Danes derive great profit from hiring their vessels in the ports of Italy, where they are in great request, on account of the Danish flag being respected by the states of Barbary, with whom Denmark takes care to be at peace. The following Table shews the number of merchant vessels, above twenty tons, belonging to Denmark in 1799, as also their tonnage and their crews:

Shipping.

Places to which they belong.	Vessels.	Tonnage.	Crews.
Copenhagen	320	50,000	4,417
India Company	8	4,724	
Gr. Bailiwick of Zealand	52	4,526	175
Gr. Bailiwick of Funen	57	2,522	109
Laaland and Falster	14	460	40
Gr. Bailiwick of Aalborg	51	2,046	214
.... of Viborg	4	114	12
.... of Aarhuus	95	4,026	349
.... of Ripen	82	4,978	1,026
Sleswick	463	40,354	2,788
Holstein	290	38,842	3,434
	1426	150,980	12,564
Norway	747	98,940	6,336
Total	2183	249,938	18,900

In 1798, the number of vessels, foreign and Danish, which entered the port of Copenhagen, amounted to 5947. There has been at Copenhagen, ever since the year 1729, a maritime insurance company. The amount of the insurances in 1796 was 5,973,812 rix dollars; that of the premiums 273,272, and that of the payment of losses 304,459. At the end of the same year the capital of the company was 663,773; and at a general meeting of the proprietors, it was agreed that the divi-

Maritime Insurance Company.

Statistics. dends should be 4 per cent. In this country, no individual is allowed to insure ships. As the navigation of many ports on the coasts of the Baltic, the Categate, and the North Sea, is at some seasons extremely dangerous, all the maritime districts are provided with licensed pilots. Those of the island of Heligoland are particularly celebrated for their skill and intrepidity. Lighthouses have been erected in various places; and at Copenhagen a collection of charts has been made for the use of navigators. The foreign commerce of Denmark has been much affected by the late war with Great Britain. In several of its branches it has been considerably impeded, and in some of them altogether suspended; but the preceding statements refer chiefly to its customary extent and channels, to which it will now soon return.

Money. The common money of exchange in Denmark is the rix dollar, which is imaginary, or if there are any in currency they are but rare. The rix dollar is divided into 96 skillings, or into 6 marks of 16 skillings each. The rix dollar is worth about 4 livres 10 sols of France; 2 florins and 3 stivers currency of Holland; 12 or 13 copper dollars of Sweden; and 1 ruble of Russia. Four rix dollars are about the value of 5 rix dollars of Germany; and $5\frac{1}{6}$ the value of a pound sterling. The only gold money coined at present in Denmark is the ducat of two rix dollars. The silver coinage are pieces of 24, of 15, of 10, of 8, of 4, and of 2 skillings.

CHAP. V.

Government, Laws, &c.

Ancient form of government. THE government of Denmark, like that of most of the Gothic nations, was originally an elective monarchy. The right of election was vested in the three estates of the kingdom, the nobles, the clergy and the commons, who were to choose for their prince a man whose person was unexceptionable, who was valiant, just, merciful, affable, prudent, a maintainer of the laws, a lover of the people, an encourager of merit, in a word, adorned with all the accomplishments and virtues necessary for the execution of so important a trust. And though due regard to the royal line was always observed, and the crown almost uniformly conferred on the eldest son, yet was the new prince generally constrained to purchase his succession to the throne by the grant of farther immunities to the subject. The supreme legislative authority resided also in the three estates, assembled in a diet by means of representatives; the executive power was vested in the king and senate, composed of the principal nobles. The king was little more than president of the senate, and commander of the army, the royal prerogative being circumscribed by the charter of rights, always ratified by the sovereign at his accession. Such was the constitution of Denmark until the year 1660, when, by one of the most singular revolutions recorded in history, from being an elective, and one of the most limited monarchies in Europe, it became entirely hereditary, and one of the most absolute upon earth; exhibiting an unparalleled instance of a people spontaneously renouncing their freedom, and investing their limited governor, almost without his concurrence, with unbounded authority. This extraordinary event (the particulars of which will be found under the head of the history of this country) was brought about by the clergy and commons, for the purpose of punishing the insolence and oppression of the nobility. After a violent altercation with that order in the diet, on the subject of taxes, these two estates proceeded in a body to the court, made a full surrender of all their privileges into the hands of the king, and proffered him absolute sovereignty. The nobles, confounded by this unexpected proceeding, and unable either to resist or escape, were compelled to feign compliance with this deed of the other estates. Accordingly, on the 16th of October, the three estates annulled, in the most solemn manner, the capitulation or charter signed by the king at his accession—absolved him from his engagements—cancelled all the limitations imposed on his sovereignty—and closed the whole by the public ceremony of doing homage, and of taking the new oath of allegiance. The revolution being thus accomplished, a new form of government was promulgated, under the title of the Royal Law of Denmark. It consists of forty articles, of which the following are the most remarkable: "The hereditary kings of Denmark and Norway shall be in effect, and ought to be esteemed by their subjects, the only supreme head on earth: they shall be above all human laws, and shall acknowledge, in all ecclesiastical and civil affairs, no higher power than God alone. The king shall enjoy the right of making and interpreting the laws, of abrogating, adding to, and dispensing with them. He may also annul all the laws which either he or his predecessors shall have made, excepting this royal law, which must remain irrevocable, and be considered as the fundamental law of the state. He has the power of declaring war, making peace, imposing taxes, and levying contributions of all sorts," &c. &c. Then follow the regulations for the order of succession—the regency in case of minority—for the majority of the king—for the maintenance, of the royal family;—and after enumerating all the possible prerogatives of regal uncircumscribed authority, as if sufficient had not yet been laid down, it is added, in the 20th article, "All that we have hitherto said of power, and eminence, and sovereignty, and if there is any thing further which has not been expressly specified, shall all be comprised in the following words: The king of Denmark and Norway shall be the hereditary monarch, and endued with the highest authority; insomuch, that all that can be said and written to the advantage of a Christian, hereditary, and absolute king, shall be extended, under the most favourable interpretation, to the hereditary king or queen of Denmark and Norway," &c. &c. Thus securely did Frederic III. fortify himself in the full possession of absolute power, now that it was within his grasp, though, when first offered, he seemed to hesitate about accepting the gift. The commons soon found, what they might have foreseen, that they had punished the nobles but had not benefited themselves. Strange infatuation! that they should find no means of humbling their oppressors, and securing their own immunities, but the establishment of an absolute government. Though the king divested the nobility of many of the prerogatives they had before enjoyed, and annexed them to those of the crown, yet did he take no methods to relieve the people, who had been the instruments of investing him with the sovereign power, but left them in the same state of slavery in which they were before, and in which they have remained almost to the present day. Justice, however, compels us to state, that few absolute princes have less abused their unlimited authority than the kings of Denmark; and that, in this country, the rigours of a despotic monarchy have generally been softened by the mild and just administration of the sovereigns who have since filled the Danish throne. Uncertain, however, must ever be the condition of a people, whose happiness depends on the mere will or caprice of a single individual.

Present form of government. Royal law of Denmark. Statistics.

Administration.

The king of Denmark is assisted in the exercise of his royal functions by a privy council, composed of such persons as he may judge most deserving of his confidence, and whom he nominates and dismisses at his pleasure. The great officers of the state are generally members of the council, and the prince royal and the other princes of the blood sit in it by right. It is here that laws are proposed, discussed, and receive the royal sanction, and that all the important affairs of government are transacted.

Government offices.

The business is prepared in the different colleges or chambers to which it more immediately belongs, and through which all applications to the council must come.

Chancery of Denmark and Norway.

These different offices of government are, first, the *Chancery of Denmark and Norway*, which was established in 1660. Its jurisdiction, at first very extensive, has been gradually circumscribed. At present the interpretation of the laws, ordonances, and rescripts, belong to it. Its authority also extends to the public education, to ecclesiastical matters, and to the poor's laws. In it are drawn up all edicts and patents, dispensations, grants, letters of nobility, of legitimacy, and of naturalization, safe-conducts, and passports into foreign countries. The archives of the state are also kept in this chancery. Of late it has been divided into several chambers, having each its separate department.

German chancery.

2d, The *Chancery of Germany*, detached from the former in 1688, and having the same jurisdiction with regard to the provinces of Sleswick and Holstein. 3. The Office of Foreign Affairs.

College of revenue.

4th, The College or Chamber of Revenue. To this chamber, which formerly had the superintendance of the whole revenue of the state, at present belongs the collection of imposts, the management of the royal estates, the direction of the territorial police, and of that of the forests and highways. Confiscations, fines, the royal lottery, and all donations to the public revenue, are also within its jurisdiction. It has also the general superintendance of the mines, and of all matters connected with the internal and commercial administration of Iceland, the Faroe islands, and Greenland.

Chamber of customs.

5th, The Chamber of Customs, established in 1760, whose province it is to collect the revenue arising from the customs and tolls throughout Denmark, Norway, and the Duchies; to superintend the inferior agents, and examine their accounts. The Chamber of Customs has besides, the direction of all matters relating to the Danish American islands and possessions on the coast of Guinea.

College of finances.

6th, The College of Finances, established in 1771. It makes up the state of the revenue and expenditure, and brings forward such representations and proposals concerning them, as circumstances may require. It has also the management of the public money.

College of commerce.

7th, The College of General Economy and of Commerce. This college, whose jurisdiction extends to every thing connected with national industry, is divided into four offices, having each their separate province.

War office.

8th, The War Office. This office has the direction of the army in Denmark and of the Duchies. There is a separate office for Norway.

Admiralty office.

9th, The Admiralty Office. This office issues all the appointments and orders for the navy, and directs every thing connected with maritime affairs. Besides these offices established in the seat of government, there are various inferior ones for particular objects, in different parts of Denmark and Norway, connected directly or indirectly with the supreme authorities. The number of individuals of all ranks employed in the colleges and other offices of administration, amounts to about four hundred.

Provinces. Stifts-ampts, &c.

Denmark and Norway are divided into eleven provinces, or grand bailiwicks, called *Stifts-ampts*, of which there are three in the islands, four in Jutland, and four in Norway. Each of these provinces is governed by a Stifts-ampts-man, a post corresponding to that of Lord Lieutenant in Britain, or of Intendant in France, to which last it approaches the nearest. The Stifts-ampts are subdivided into districts or bailiwicks, called *ampts*, under the superintendance of inferior governors, called *ampts-men*. The Duchies of Sleswick and Holstein have a Governor-general, who resides in the castle of Gottorp. The cantons of Eystersted and Ditmarsen, the Lordship of Pinneberg, and the county of Rantzau, form likewise distinct governments; and the city of Altona also has a separate governor with the name of President.

Policy of the court in the disposal of public offices.

Ever since the revolution in 1660, the court of Denmark had been disposed to employ in the public offices of the state foreigners, especially Germans and persons of humble rank and fortune, in preference to natives and the ancient and more wealthy nobility. The nobles were sufficiently ambitious of procuring employments under government, which indeed is necessary for protecting their estates from the exorbitant exactions of the public collectors. But foreign adventurers, and men of low condition, were more convenient and pliant tools of the minister or favourite. This policy, the source of so much discontent and oppression, government solemnly renounced, by the publication of a law on the 1st of January, 1776, according to which, none but natives of the Danish states were to be admissible into public offices and employments, excepting in the case of such extraordinary merit as might justify the exception. This law, which was declared to be a fundamental law of the kingdom, was received with universal applause.

Royal establishment.

The court of Denmark was formed by Christian V. on the model of that of Louis XIV. which he had seen during his travels in France. The principal establishments are still retained, but on a much less expensive footing. Indeed, an attention to economy pervades all the departments of the Danish government. There are stated days for levees and the grand galas of the court.

Royal palaces.

The king's guard consists of several companies of infantry and troops of cavalry; and the chief ensigns of majesty at this court are of a military kind.

Frederic's place.

The chief residence of the Danish court is Frederic's Place, in Copenhagen, which was purchased for the royal accommodation after the burning of the vast and magnificent palace of Christiansburg, which the Danish system of economy has hitherto prevented from being rebuilt.

Rosenberg.

There is also in the capital the palace of Rosenberg, built by Christian the Fourth, which has not been inhabited of a long time. There are also, in different parts of the country, castles and villas belonging to the royal family.

Fredericsborg.

Fredericsborg, about eighteen miles from Copenhagen, the principal building of which is a magnificent edifice.

Fredensborg.

Fredensborg, or the Castle of Peace, so named because there the peace was signed with Sweden in 1720. It is situated in a delightful country, about eight miles from Cronberg.

Marienburg.

Marienburg, a villa situated on a height overhanging Cronberg, and commanding a beautiful view.

Hirscholm.

Hirscholm, fourteen miles from Copenhagen, in a very unfavourable situation, in building and embellishing of which Christian the Sixth expended very large sums of money.

Jaegersprus.

Jaegersprus, about thirty miles from the capital, in the gardens of which palace monuments have been erected to the illustrious men of the country;

Fredericsberg.

and *Fredericsberg*, built on an eminence in the neighbourhood of Copenhagen, which is the usual summer residence of the king and royal family. The kings of Denmark, in their public deeds, take the following title: " N. N.

Statistics.

Titles of the king of Denmark.

by the grace of God king of Denmark and Norway, of the Goths and Vandals, duke of Sleswick and Holstein, of Stormarn, and of Ditmarsch, count of Oldenburg and of Delmenhorst." The king's oldest son takes the title of Prince Royal, and the other children that of hereditary prince or princess.

Arms.

The arms of Denmark and Norway are three lions. To these are added separate arms for the duchies; and three crowns, which are also in the arms of Sweden, having been assumed by the sovereigns of both countries ever since the union of Calmar.

Degrees of nobility in Denmark;

The degrees of nobility in Denmark are two; those of counts or earls, and barons. The counts are entitled, illustrious and high lord; the barons, illustrious lord. The counts have the privilege of erecting canopies of state, and their eldest sons enjoy the title of barons. The number of earldoms or counties in Denmark and Norway is about seventeen, and of baronies fifteen. Besides those nobles who derive their nobility from their estates, which are royal fiefs, there are other families invested with the same titles, simply as personal distinctions.

In Sleswick and Holstein.

The nobility of Sleswick and Holstein form a distinct body, and enjoy more extensive privileges. Every thing connected with the common interests of this body is discussed in a general convention, held at stated times in the city of Kiel, when very disagreeable debates frequently take place. There are in Denmark two orders of knighthood; the order of the elephant, and the order of Danbrog. Of these, the first is considered as the most honourable, and conferred only on persons of the highest distinction and merit.

Gradations of rank.

The inhabitants of Denmark may, therefore, be divided, according to their rank, into the five following classes: 1st, The nobility who have privileged fiefs in the kingdom. 2dly, The titular nobility; to which class belong the companions of the two orders of kighthood—those counts and barons who are not possessed of counties and baronies—and the persons filling the higher offices of the state, whether civil, military, or ecclesiastical; all of which confer on those who hold them a certain nobility during their lives: and it is very common in this country to obtain, merely for the purpose of acquiring rank, the title of an employment which the person never exercises, and from which he derives no emolument, but for which, on the contrary, he often pays a considerable yearly sum. 3dly, The inferior clergy, lawyers, and students. 4thly, The merchants and citizens of the great towns: And, 5thly, The seamen and farmers.

CHAP. VI.

Laws.

Laws.

The laws of Denmark are remarkable for their equity, plainness, and brevity. They are expressed with so much precision, and so little subject to ambiguity, that almost the meanest capacity may comprehend them: The natural consequence of which is, that in this country lawsuits are rare, the number of lawyers is small, and the legal profession by no means lucrative.

General character.

The Danes boast not a little, and that not without reason, of their superiority in this respect to the most refined and learned people of Europe. It is asserted, however, that, notwithstanding of the excellency of their laws, it is difficult for the poor to obtain justice against the nobility and the favourites of the court.

Danish code.

The present code of Danish laws was published by Christiern the Fifth, and is founded on the code of Valdemar. It is comprised in one quarto volume, written in the language of the country, and divided into six books. The first book treats of the procedure of the courts of justice; the second, of the ecclesiastical government; the third, of offices and the different states of persons; the fourth, of the maritime laws; the fifth, of the different means of acquiring property, and of contract; and the sixth, of crimes and their punishments.

Courts of law.

With regard to the courts of justice, there are three gradations in Denmark:—First, The *Herredfogds*, which are the lowest and most circumscribed, similar in their nature to the English leetcourts.

Inferior courts.

These are established in the various districts throughout the country; are composed of a judge and a clerk, and meet once in the week. Corresponding to the Herredfogds in the country districts, are the *Byefogds* in towns and cities. Next, and superior to these, is the *Landstag*, or provincial court; of which there are five in Denmark, those of Zealand, Fionia, Jutland, Bornholm, and Falster. To these, which meet every month, there lies an appeal from the Herredfogds and Byefogds; which appeal must be taken within the space of half a year.

Supreme court.

The supreme court of the Danish dominions, called *Hight-right*, is held at Copenhagen. Here all causes are determined in the last resort, and the nobility have the privilege of being amenable to it alone.

The king nominally presides.

The king opens this court in person every year, with great solemnity, and delivers to the judges what instructions he thinks necessary. He is supposed to preside in it at all times; and a throne is erected for him, to which the lawyers address themselves in their pleadings, and the judges in giving their opinions.

Terms.

This court sits the whole year, with the exception of the months of July, August, September, and the half of February. This is the only court of justice in which verbal pleadings are allowed, the processes in all the inferior courts being conducted in writing. No appeals are received by this court, if not taken within a year and six months. The judges, who have fixed and adequate salaries, are some of them nobles, and some of them commoners. Their decision is final in all causes relating to the fortunes of the subject; but in such as regard their honour or their lives, the king has reserved the right of revision.

Forms of procedure.

An action at common law, commences by the plaintiff citing the defendant before the proper tribunal.

Civil causes.

This he is at liberty to do, either by word of mouth before two witnesses, or in writing. The claims of the parties, written in clear and concise terms, are then laid before the judge, who, besides, may put to them such questions as he apprehends will tend to an elucidation of the subject in dispute. After having fully heard the proofs on both sides, the judge solemnly pronounces sentence. Few causes occupy more than one sitting in either the supreme or inferior courts; and none can be extended beyond six weeks. The clerks and registers, too, are obliged to bring the whole process within a limited number of sheets, including the allegations, proofs, and sentence. A certain price is affixed to each sheet, and thus the parties may know to a certainty the utmost expence of a proceeding. When an appeal is brought before a superior court, the inferior judge is likewise summoned to appear and defend his decision, and he is sometimes obliged to render satisfaction to the party injured by an unjust sentence.

Criminal cases.

Criminal cases are conducted much in the same form as those of a civil nature. The judge, within whose jurisdiction the crime has been committed, empowers

Statistics. two lawyers to manage the cause; one to make proof of the accusation, and the other to act in behalf of the accused. If, however, the prisoner refuse the assistance provided for him, he is indulged with counsel of his own chusing. No criminal is condemned but on the testimony of sufficient witnesses. After condemnation, the privilege of appealing to the provincial, and from thence to the supreme court, is allowed to all who insist upon it. If the punishment extend to the loss of life, the judgment of none of the courts can be final, but, as has been already stated, a report must be made to the king himself in council, without whose approbation no sentence of death can be carried into execution.

Torture. The Danish law admits of the shocking practice of torture in two cases, after the accused has been fairly and lawfully convicted, and sentenced to lose his life: These are, the cases of murder and high treason. The intention of the law, by this permission, is to draw from convicts a discovery of their accomplices. But a statement of the case must be laid before the sovereign and his ministers for their consideration, and a warrant, signed by the king himself, must be obtained, before any proceedings of this merciless kind can take place; and it is but justice to state, that this cruel practice is very seldom resorted to, more than twenty years sometimes elapsing without the occurrence of a single instance. The law on this head was, however, shamefully violated in the case of the unfortunate minister Count Struensee, who, before his trial, was compelled, by the dread of the torture, to confess himself guilty of criminal intercourse with the queen. The iniquity of the proceedings on this occasion, will long remain a stain, if not on the Danish name, at least on the characters of the ruling party at that period. It is to be regretted, that the excellency of the Danish laws can be so easily rendered unavailing by the dispensations of the court.

Trial by jury. In cases of murder, and also for ascertaining the limits of estates and property in land, the law of Denmark allows of the trial by jury. The jurors, eight in number, must be men of good character, and in nearly the same condition of life with that of the person whose judges they are constituted. Besides this resemblance between the Danish and the British jurisprudence, there is another instance of similitude, which appears rather more singular, when we consider the political principles on which the present constitution of Denmark is erected.

Imprisonment. This is that excellent law, according to which no individual can be imprisoned unless he is seized in the act of committing a crime deserving of death or of bodily punishment; or unless he has acknowledged himself guilty before the proper magistrate; or been convicted in a court of judicature. In virtue of this law, individuals lying under an accusation have, till it is lawfully proved against them, on finding security for their appearance, a right of enjoying their personal freedom. In whatever country so valuable a privilege is allowed to subsist, the inhabitants may justly boast of possessing no small share of liberty; and if the Danes have, as they assert, preserved this law inviolate, and in its full force, they are a much freer people than they are generally represented, or than the subjects of an absolute monarchy could be supposed to have been.

Special courts. Besides these general courts of law, there are several others instituted for special objects. Such are the military tribunals of the two kingdoms, the tribunals of the mines, the various tribunals of commerce, and the tribunal of inquisition at Copenhagen for the discovery of robberies and thefts.

Commissions. Causes are often taken out of ordinary courts, and tried by commissioners appointed for the purpose. In these cases, one of the parties is generally a man of influence, who obtains such an appointment with some sinister view.

Courts of conciliation. Very great advantages have resulted from the tribunals of conciliation, established in 1795. If these tribunals succeed in reconciling the parties, the agreement is registered, and it has then the same validity as the sentence of a court of law; but if they fail in this object, the proceedings are to be regarded as never having taken place; no record is made, and no expences are incurred. The second chapter of the Danish code, treats of the ecclesiastical government, which shall be considered under the head of Religion.

Of the different states of persons. With regard to the third chapter, the state and privileges of the nobility have already been mentioned, and it remains only to notice the condition in which the Danish law considers the lower classes.

Condition of the peasants. These, with the exception of the inhabitants of the towns and cities, and a few of the peasants who had acquired their freedom, were, until lately, regarded as the property of the nobles, were attached to their estates which they could not leave, and were bought and sold with the soil. For a long time past, men of benevolence and enlightened views were convinced, not only of the injustice and inhumanity, but also of the impolicy of this state of things;

Edict for their emancipation. and several of the nobility, encouraged by the example of the royal family, had already emancipated their peasants, of which praise-worthy conduct they reaped the reward, not only in the gratitude of these hitherto degraded men, but also in the improvement of their estates. At length, this important object was universally and finally accomplished by the publication of an edict in 1788, ordaining the gradual abolition of the servitude of the peasantry; and all the inhabitants of Denmark were free on the 1st day of January, 1800.

Obelisk to commemorate this great event. To preserve the remembrance of this emancipation, an obelisk has been erected in the neighbourhood of Copenhagen, on the Roschild road, which is the most frequented by the peasants coming to the capital, on which is written the following words: "The king knows, that civil liberty, regulated by just laws, produces the love of one's country, and courage to defend it; the desire of instruction, a disposition for industry, and the prospect of happiness. He has therefore ordained, that servitude shall cease, and that order and promptitude shall regulate the execution of the rural laws, to the end, that the free, courageous, enlightened, industrious, and virtuous peasant may become a valuable and happy citizen." The base of the obelisk is adorned with emblems and inscriptions, and supports four marble figures, representing fidelity, rural industry, courage, and patriotism. The prince royal laid with his own hands the first stone in 1792. The inscription denominates him, "Son of the king and friend of the people." This monument, 48 feet in height, cost 14,000 rix-dollars, raised by subscription. The traveller, in stopping to contemplate it, will bless the names of the prince, of the minister, and of the individuals who, in spite of prejudice and of self-interest, accomplished so beneficial a reformation.

Cap. 4. of the Danish code. The fourth chapter of the Danish code, relates to contracts, and the different means of acquiring property.

Marriage. Marriages are regulated here in nearly the same manner as in other Lutheran countries. A divorce may be obtained in the case of adultery, of wilful desertion, or of impotence existing previous to the conjugal union. Amongst the nobles and persons of privileged rank, nothing more is necessary to constitute marriage than a simple consent in the presence of witnesses. The in-

Statistics.

ferior orders must be married by a clergyman. Man and wife have all their goods and property in common, and any convention, contrary to this regulation, will be null, unless confirmed by the king. The survivor inherits the half of their joint fortunes; the other half is divided among the children, of which the said survivor shall, moreover, take a child's portion, but in case of a second marriage, this must be restored to the children. The women of this country are always under guardianship. When married, their husbands are their guardians; when unmarried, or widows, their nearest relation. They never attain majority but by dispensation.

Contracts.

Contracts drawn up in the presence of two witnesses, and signed by the contracting parties, are binding. Verbal bargains, in the hearing of witnesses, are likewise legal. Deeds, transferring hereditable property, must be registered.

Successions.

In Denmark, no person can succeed to the property of another, but by the path which the civil law points out, except the king, by a particular privilege, confers the power of making a testament. This permission, it is said, is seldom refused when there are no children, but when there is issue it cannot be granted. It is lawful, however, for husband and wife, who have no children, to dispose of the half of their property as they choose, and even of the whole, if it be for pious uses. Children succeed to the fortunes of their parents in the following manner: a son has double the portion of a daughter, and can take in preference any manor or freehold in the succession. The grandsons are admitted by right of representation, which indeed extends to all the descendants. If there are no descendants, the father succeeds alone. In default of the father, the mother succeeds conjointly with the brothers and sisters, and their posterity; afterwards the ascendants and collateral lines are admitted. The law makes no distinction from which side the property comes, but admits the paternal and maternal line to partake equally of the succession, preferring always those who are in the nearest degree. Any person having an estate in freehold lands of 2400 acres, may fix it by a special entail in his family, in what manner and on what conditions he shall think proper. The proprietors of freehold lands have the power of giving to one of their sons double the portion of the others, and if they have no sons, they may make the same regulation with regard to their daughters. Illegitimate children are treated with more humanity by the laws of this country than by those of most others. If the father acknowledges them before the legal tribunals, they obtain half the portion of the legitimate children, if he has any; and if he has none, they succeed to his whole property.

Of crimes and punishments.

The mode of procedure before the criminal courts has already been stated. The criminal code of this country is, in general, distinguished by its wisdom and its humanity.

Irreligion.

The laws enacted in a bigotted age, against apostacy from the established religion, heresy, sacrilege, profanation of holy days, and negligence in attending public worship, have here, as elsewhere, been greatly relaxed by the progress of toleration.

Treason.

The crime of treason has been regarded in a more heinous point of view since the monarchy was rendered absolute and hereditary. The principal article of the Danish law on this head runs thus: Whoever shall accuse the king and queen, with a view to dishonour them, or make any attempt on their life, or on that of their children, shall forfeit his honour, his life, and his property. Before execution, his right hand shall be cut off, his body shall be quartered and exposed on the highway, and his head and hand hung upon a gibbet. If the criminal is noble or of high rank, his arms shall be broken by the hangman, and his children degraded from the rank of nobility. Murder is punished with death, and the criminal is beheaded. Child-murder is not excepted, but the punishment is almost always commuted.

Robbery, theft, &c.

Robbery, housebreaking, theft, and other crimes of this nature, which, in other countries, are punished with death or banishment, are here punished by imprisonment or condemnation to hard labour for a limited time, or for the remainder of their lives. But if these criminals make their escape, and repeat their guilt, their lives are forfeited. The more heinous crimes, as treason, murder, robbery, &c. are seldom heard of, and capital punishments are rarely inflicted.

Maritime laws.

The following are some of the most important of the maritime laws of Denmark: No contracts between the proprietors of vessels and their captains are binding, unless they are in writing. Sailors are to be treated according to the agreement entered into with them. But captains may leave such as are seditious, even in foreign countries, and may confine those guilty of crimes or misconduct until their return. But he is required to do this only with the advice of the ship's counsel, or of some of the most respectable of the crew. If the person engaged as a pilot, shall occasion the loss of the ship by his want of skill, he is held liable to pay the damage; and if he be unable to do this, he is punishable with death. The means employed, however, by government for the instruction of seafaring people, render it seldom or never necessary to resort to this almost only rigorous statute of the Danish code. When a captain of a merchant ship is on a voyage in any foreign country, and is in want of money, he is authorised by the law to sell any part of the cargo entrusted to him for the supply of his wants. With the view of making the interests of seamen subordinate to those of commerce in general, the legislature has given to the captain of a vessel, in many instances, the power of breaking his contracts with his men. If, for example, he has engaged them to go a voyage to the Mediterranean, and afterwards finds he can sell her cargo to much greater advantage in the West Indies, they are obliged to make that voyage along with him. In former times, all ships driven ashore on the Danish coast, were immediately robbed and plundered; and even the nobility and Romish bishops, whose lands were situated on the sea-shore, drew from this barbarous custom a considerable revenue. In abolishing this savage practice, the kings of Denmark have experienced the strongest opposition; and the attempt cost Christian the Second his crown and his liberty. The following are the enactments at present in force with regard to shipwrecks: The shipwrecked goods must be deposited by the inhabitants of the coast, in a place of security, and no person can oblige the captain to sell them. Whoever shall carry off the effects of a ship which has been wrecked, to the value of 50 marcs, shall be hanged as a felon. Shipwrecked effects unclaimed at the end of a year and a day, after paying the expence of salvage, belong one half to the king, and the other to the person having the right of escheat in the district. On the subject of insurances and other matters of this nature, the Danish code is conformable to the principles adopted by all commercial nations.

Laws of Sleswick and Holstein.

The duchies of Sleswick and Holstein have preserved their own ssparate institutions and laws; and the administration of justice is much more complicated in them than in the Danish states.

Sleswick.

The laws of Sleswick are contained in the ancient code of Jutland, published by

Statistics.

Valdemar II. in 1240. It is easy to perceive, however, that these laws must have been subjected to many alterations in modern times. Several districts and cities have laws of their own, as Heligoland, Femern, Eystersted, Brested, Husum, and Fredericstadt. The laws of Holstein are contained in several voluminous collections, and consist of a number of charters, ordonances, and rescripts, which have appeared at different periods. They acknowledge the Roman law in some instances, and the decrees of the diet of the empire have also some authority. The police of Denmark is in general the same as that of the other countries of Europe. It embraces many useful regulations, and is by no means of that inquisitorial description which is commonly found under arbitrary governments. The details will be given under the descriptions of the cities.

Police.

CHAP. VII.

Finances.

Finances. Revenue. Demesnes.

The revenue of the kings of Denmark arise from the following sources. From the royal demesnes, which, before the revolution, formed their only income. These have since been portioned out to different proprietors for the advantages of agricultural improvements, and the quit-rents still produce a considerable revenue. From the tithes in Denmark and Norway, which, since the Reformation, the king has divided with the clergy. The king's share of the tithes of Denmark have been sold to ten individuals. From licences for the distillation of spirits, from the mint, from grants and dispensations, from licences for hunting and shooting on the royal estates, from lotteries, from the toll on the Sound, &c. In 1770, the toll of the Sound produced 459,890 rix dollars; and since that time it must have produced yearly, at an average, at least half a million. Besides these, which are considered as more peculiarly the rights of the crown, the necessities of the state have imposed various other taxes. Of these, the land-tax is one of the most considerable. This tax is levied, according to a valuation, even originally, in many respects objectionable, made in the reign of Christian the Fifth. The standard employed in this valuation was the Danish measure of the ton of *Hartkorn*, which is such an extent of land as would sow three tons of grain, one of rye, one of barley, and one of oats. The quantity varies of course according to the quality of the soil, but the ton of Hartkorn may be considered, on an average, about six English acres. The pasture grounds, woods, and mills, are likewise estimated by this measure. The land tax per ton of Hartkorn, is for the arable and pasture grounds, one rix dollar, forty-two skillings, and for the woods and mills, one rix dollar, eighteen skillings, amounting to about one shilling and eightpence sterling per English acre. The lands of the nobility are exempted from this tax. The privileged lands throughout all Denmark was, in 1786, estimated at 55,377 tons, and those subject to the tax, at 316,100. Besides the above, the possessors of land are subjected to another tax, called the corn-tax, paid partly in money, and partly in kind, which amounts to about one rix dollar, one marc, four skillings per ton for the arable and pasture grounds, and to three marcs ten skillings for the woods and mills. In 1800, in the assessment for the following year, the price to be paid for the grain was fixed by government, and the privileged lands, and even those of the counts and barons, were also taxed, and at the same rate with the others. The valuation of the duchies was made in 1657. Some districts have been valued more recently, and are taxed by the plough, which is nearly equivalent to nine tons of Hartkorn. All estates are subject to the tax, and pay between three and four rix dollars per plough monthly. A poll-tax has long been levied in the Danish dominions. Formerly the inhabitants of the country only were subjected to it; but in 1762, it was extended, without distinction, also to those of the cities and towns. Every individual above twelve years of age, pays one rix dollar. The children of peasants who are farmers, and those of day-labourers, do not pay this tax until they have completed their sixteenth year. This tax has been abolished in Norway and another substituted in its place, the peasants having considered it as a badge of slavery. The towns of Altona and Bornholm are also exempted from it on the payment of an annual compensation. The tax formerly levied on marriages, was very properly suppressed in 1792. It still exists in Copenhagen as a city-tax. A tax on ranks was introduced in 1764, and laid in the following proportions.

Tithes, &c.

Toll of the Sound.

6	15
7	12
8	8
9	6

Widows pay the half of this tax, with the exception of those whose annuity is below a hundred rix dollars. In 1768, a tax was laid on all places and pensions according to the following gradation:

Tax on places and pensions.

Incomes of	100 rix dollars to	150 taxed at	2 per cent.
	150	200	3
	200	250	4
	250	300	5
	300	350	6
	350	400	7
	400	450	8
	450	500	9
	500 and upwards		20

The clergy were at first taxed at 10 per cent. on their incomes of every description; but since 1770, they have been rated in the same proportions as the civil and military officers. All collateral successions have been taxed at 4 per cent. since 1792. The stamp duties were introduced by Frederic the Third in 1657. All the proceedings of the courts of justice, commissions, letters patent for all public employments and titles: All kinds of contracts, conventions, obligations, receipts, and all public acts, must be written on stamped paper. The lowest stamp for bonds, &c. is two shillings, and the highest for all pecuniary bargains is ten pounds sterling. The smallest receipt stamp is two-pence, and the highest L. 2, 8s. The patent for creating a count with a county, must be written on a stamp of the value of L. 60; for a baron with a barony, L. 40. The commissions of all the great officers of the crown and state, of the first class, must be written on a stamp of L. 20, of the second class L. 16; thus diminishing with the rank and class until the lowest is only sixteen shillings. The customs and excise form one of the most productive branches of the public revenue. This department is regulated on principles similar to those established in other commercial states. The expence of

Stamp duties.

Customs.

Statistics. Collectors, &c. collecting the taxes is by no means great. In the cities and towns, the chief magistrate superintends the collection. In the country, collectors are appointed, of which there are thirty-three for Denmark, forty-one for Norway, and thirty-one for the duchies. The officers of the customs amount to fifty-five in Copenhagen, two hundred and thirty-five for the rest of Denmark, two hundred and forty-four for Norway, and ninty-nine for the duchies. Amount of public revenues at different periods. In 1699, there passed into the public treasure of the states nearly 3,500,000 rix dollars; in 1726, nearly as much; in 1756, 4,955,800; in 1770, 6,081,830; from 1785 to 1787, about 7,270,172. The following Table exhibits the particulars of this last receipt.

Expenditure. Such was the amount of the whole revenue of Denmark in 1785, 7,270,172 rix dollars 5 skillings, or about £1,400,000 sterling. Since that period it has been increased in all the Danish states, particularly in Norway, and may now amount to upwards of a million and a half. The court establishments, the royal household, the civil list, the army, and navy, form the principal objects of the ordinary expenditure; the amount of which, in 1770, was nearly 6,158,710 rix dollars—in 1786, 7,579,734—and in 1790, 6,525,000. The items of this last year, which is about the average of the ordinary expences of the Danish government, was, exclusive of some small sums for particular purposes, as under:

	Rix dollars.
Court and royal household	250,000
Establishments of the prince and princess	180,000
Civil list	707,500
Extraordinary bounties	111,000
Pensions and ordinary bounties	120,000
Army	2,080,000
Navy	1,200,000
East India possessions	180,000
Carry over	4,828,500

Statistics.

Bounties for the encouragement of commerce, mines, and manufactures	300,000
Annuities	27,000
Buildings and repairs	120,000
Interest of the national debt	1,100,000
Sinking fund	150,000
Total	6,525,000
or	L. 1,262,903

National debt.

The national debt in 1758 amounted to 4,250,250 rix dollars. In 1771, it was at home 7,139,762 rix dollars, and abroad 10,051,184, making in all 17,190,946. A system of stricter economy was introduced into all the public departments of the state in 1785, and at the same time means were taken for rendering the revenue more productive. The public debt has, in consequence, been considerably reduced, though no doubt the disturbances in Europe which have since taken place, have much retarded the plans of liquidation adopted by the Danish government.

CHAP. VIII.

Military and Naval Establishments.

Army. Regulars. Militia.

Army.—The forces of Denmark consist of regular troops and of militia. The number of the former varies according to circumstances, and is composed partly of natives and partly of foreigners, chiefly Germans. Formerly every person who possessed 360 acres of land was obliged to furnish one man for the militia, and to pay half the expence of a man for the corps of reserve. In 1788 this faulty system was abolished, and the militia is now raised in the following manner. Every peasant at his birth is enrolled in the militia lists. The age during which they are liable to be called upon to serve, is from twenty-one to thirty-six; and when vacancies take place, the oldest on the roll of the district must supply them. The term of a militiaman's engagement is eight years, and before the expiration of that period, he cannot quit his district without leave from the constituted authorities. The militia of this country are not formed into separate regiments, but are attached to the regiments of the line. They are occasionally exercised in small bodies on Sundays and holidays, and are embodied once every year, at which time they join their respective regiments. In Denmark and the duchies, this annual service continues about a month, and in Norway twelve days. The clothing of the Danish army is furnished by an extensive manufactory established by government for this purpose. The prevailing uniform is red. The regulars are clothed every three years, the militia only every twelve. The troops of the line are paid according to the following scale:

Pay of the troops.

A colonel	1740 rix dollars per annum.
Lieutenant-colonel	852
First captain	600
Second captain	228
First lieutenant	156
Second lieutenant	133
Ensign	114
Serjeant	18 skillings per day.
Corporal	12
Private	6

A militiaman has five rix dollars yearly, besides two skillings per Danish mile (4½ English) when marching to the station of his regiment, and the pay of a soldier while he remains there. The regular troops are stationed in the cities and fortresses, and lodged at the expence of the citizens. The horses of the regular cavalry are maintained partly at the expence of government, and partly by the farmers. The army is supplied with officers from the Academy of Land Cadets, instituted by Frederic the Fourth, where seventy-four cadets are instructed in the military sciences at the royal expence. The whole military force of Denmark, in 1796, was as follows:

Cavalry.	
In Denmark and the duchies	6,066
In Norway	4,349
	10,415
Infantry.	
In Denmark and the duchies	30,396
In Norway	30,509
	60,905
Corps of engineers	35
Corps of artillery	3,299
Total	74,654

Of the above, 50,880 are militia, 7808 being cavalry, and the remainder infantry. In 1801, a new militia was raised, called *the defence of the country,* and composed of all those who had served in the ordinary militia, and who had not attained the age of forty-five. Denmark possesses strong natural ramparts. The most important fortifications are those of Copenhagen, of Fredericia in Jutland, of Rendsburg, and Gluckstadt in Holstein, and of Fredericshall, Fredericstadt, Aggerhuus, and Fredericswærn in Norway.

Navy.

Navy. The Danes, from their insular situation, have long excelled as a maritime people, and are still the most numerous, as well as the most experienced, sailors of any of the kingdoms on the Baltic. In the beginning of the year 1801, the Danish navy consisted of 22 ships of the line fit for service, and seven which were dismasted; of 15 frigates, four brigs, 13 gun-boats, and three praams, besides several vessels on the stocks. Since the above period, this naval force has been greatly reduced, or almost entirely annihilated, first by the victory of Lord Nelson, and afterwards by the seizure of their whole fleet by a British armament in the month of August 1807. A considerable time must elapse before Denmark can again appear powerful at sea. The building and refitting of the ships of the Danish navy is intrusted to a particular board appointed for that purpose, to whose examination all plans and models are submitted. The greater part of the oak employed in the naval arsenals is procured from Germany, by contract with the king of Prussia. Holstein produces oaks, but not in sufficient quantity, and they are preserved for cases of extreme necessity. All the cannon, shot, anchors, and iron work are cast in Norway. Flax, hemp, and masts, are procured from Russia, and pitch and tar from Sweden. The Danes have manufactories of cordage and sails, but they do not yield sufficient for the use of the fleet. The remainder is procured from Russia and Holland. The principal station of the Danish navy is the harbour of Copenhagen, which lies within the fortifications. Four or five ships of the line

Statistics.

are generally stationed in the ports of Norway, a frigate off Elsineur, another off the isle of Funen, and a smaller vessel in the Elbe. The number of registered seamen is 14,600, divided into two classes; the first comprises those furnished by the maritime districts, who are allowed to engage in the service of merchant ships trading to any part of the world. Each receives two rix-dollars annually from the crown, and is subject to recal in case of war. The second comprehends the fixed sailors, who are constantly in the employ of the crown, and amount to about 4000, which are divided into 40 companies, and are stationed at Copenhagen for the ordinary service of the navy and the work of the dock-yard. When not at sea, they receive each two rix-dollars per month, besides flour and other provisions; every two years a complete suit of clothes, and every year breeches, stockings, shoes, and a cap. When they sail, their pay is augmented to five rix-dollars per month. The marine artillery consists of 800 men in four divisions. A ship of 90 guns, with its full complement, carries 850 men, of 70 guns 700, of 64 guns 600, of 50 guns 450, and a frigate of 36 guns 250. The chief nursery for naval officers is the Academy of Marine Cadets, instituted by Frederic IV. in 1701. The foundation is for 60 cadets, who are maintained and instructed in the theory of navigation at the expence of the crown. Beside the original number, other youths are admitted under the name of volunteers, at their own expence. Every year they make a cruise on board a frigate.

Seamen.

CHAP. IX.

Population.

Population.

The population of Denmark, previous to the last century, is altogether uncertain. In 1720, government appointed registers to be kept of the births, deaths, and marriages; but it was not until 1775, that these could be consulted with any degree of confidence. An enumeration of the inhabitants of all the Danish states in Europe was made in 1769, of which the result was 2,017,127 souls. But it ought to be observed, that the army and navy were not included in this enumeration, and that it took place in summer, when many individuals, and particularly seafaring people, are absent from their homes. Besides, the fear of its being only the forerunner of some new tax, induced many to avoid it. The following Table of births and deaths exhibits the progress of population in the Danish states from 1785 to 1799.

Years.	Births.	Deaths.
1785	64,920	68,691
1786	66,123	65,759
1787	64,033	61,901
1788	68,382	61,308
1789	68,134	61,299
1790	67,919	57,006
1791	70,131	56,105
1792	75,597	56,150
1793	72,368	56,752
1794	73,246	57,906
1795	71,562	57,746
1796	71,617	55,520
1797	76,468	58,202
1798	77,750	60,884
1799	77,284	59,878

The following Table proves the number of marriages also to be increasing.

Years.	Marriages.	Years.	Marriages.
1777	14,189	1797	20,930
1795	18,712	1798	21,050
1796	19,600	1799	18,267

The present population of the Danish dominions is estimated at two millions and a half; and though there is reason to think that it considerably exceeds that number, it is yet by no means adequate to the natural resources of the country. Denmark enjoys a salubrious and temperate climate, a soil by no means unfruitful, and a situation favourable to commercial industry. But under what latitude, or on what soil, could population keep pace with the intentions of nature, when that class of the inhabitants, who ought to cultivate the earth and raise the means of subsistence, are reduced to that state of servitude and degradation in which the Danish peasants have been so long held. To this prominent obstruction, are to be added several others, such as the laws imposing restraints on industry and commerce, the tax on marriages, the public burdens bearing so heavy on a great part of the community, and the faulty administration of the poor's laws. These obstacles have now in a great measure been removed, and the population has already felt the effects in the most striking manner.

CHAP. X.

Religion.

Religion.

Until the ninth century, the Danes, as well as the other Scandinavian nations, were professors of the religion of Odin, the celebrated conqueror, legislator, and prophet of the North. About this period, Christianity was introduced into Denmark by St Augarius, bishop of Hamburgh and Bremen, in the reign of Harold Clachius, the first Christian monarch. The principles of the Reformation found their way into this country at an early period, and notwithstanding all the efforts of the Catholic clergy to stop their progress, Lutheranism was formally established in 1536. The government of the Lutheran church of Denmark appears to form a medium between the English hierarchy and the discipline of the Calvinistic church. The Bishops, who act only as superintendants, have no temporal jurisdiction. Their authority extends no farther than is necessary for maintaining good order and decency in the church, and advancing the interests of religion. They confer the sacred orders, inspect the conduct of the clergy, whom they exhort, reprove, or even suspend, as circumstances require, examine the state of the schools, inquire into the management of the poor's funds, &c. within their diocese, which they ought to visit at least once in three years. Every diocese is divided into a certain number of districts, in each of which there is an archdeacon, who represents the bishop in his absence, and exercises all his functions. These archdeacons are elected by the votes of the ministers of the several parishes of the district. Twice a year a general assembly is held of the archdeacons of the diocese in which the bishop presides, and which is also attended by the grand bailiff or Stifts-amptsman on the part of the king. These assemblies take cogni-

Statistics.

sance of all ecclesiastical matters in the diocese, and hear appeals from the judgments of the archdeacons. There lies an appeal from the sentences of these assemblies to the supreme tribunal of the kingdom, which judges of all cases, both ecclesiastical and civil, in the last instance. In ecclesiastical causes, two bishops have seats in this court. Besides the diocesan assemblies and the archdeacons courts, there is, in every parish, an assembly composed of the elders of the church, and the rector or minister, who is the president, whose province it is to watch over the manners of the people, and to correct those disorders which the laws do not punish. There are altogether in the Danish states, thirteen bishops, two hundred and twenty-seven archdeacons, two thousand two hundred and sixty-seven parochial clergy, and one hundred and ninety-five chaplains. There are in Denmark no archbishops, but the bishop of Zealand, who is first in rank, and the bishop of Aggerhuus, are metropolitans. The revenues of the clergy arise chiefly from tythes, glebes, surplus fees, and the voluntary offerings of the parishioners at the chief festivals. The bishops have an income of from 400 to upwards of 1000 pounds sterling. In Denmark, the parochial livings seldom exceed L. 400 or fall short of L. 60 per annum, Jutland excepted, in which peninsula there are some not worth L. 20. In Norway, the highest may be rated at L. 200, and the lowest at L. 60. In Iceland, some parishes do not produce more than L. 3 or L. 4 a year. A clergyman's widow receives the whole profit of her husband's cure for the year immediately following his decease, and a pension from his successor amounting to the eight of his annual income. There is also in every diocese a fund for the widows of ecclesiastics, from which they draw annuities proportioned to the rates paid into it by their husbands. The church livings are in the gift of the king, of the possessors of the privileged estates, and sometimes of private individuals. A few are in the nomination of the parishes themselves. The ministers of the established church of Denmark are deservedly held in high estimation; and in no reformed country do they possess greater influence over the people. To this they are probably in a good measure indebted to the practice of confession still retained in this church, and to which all, even those of the highest rank, must submit. In the pulpit too, they assume the authority of the ministers of Christ, and reprove with great freedom men of the first quality, who practise public vices; nor are any liberties consistent with the duties of their function ever taken amiss. It was not until towards the middle of the last century, that any other than the established religion was tolerated in the Danish states. But liberty of conscience is now recognised, and the greater part of the penalties imposed on non-conformists are either rescinded or softened. In the reign of Frederic the Fourth, a society was established at Copenhagen, denominated the *College for the propagation of the Gospel.* This society, whose funds are derived from the bounty of the king and other contributions, extends its labours, and often with the happiest effects, to Lapland, Greenland, and Asia.

CHAP. XI.

Literary Establishments, &c.

Education.

By the laudable exertions of government, and of benevolent individuals, the means of education are placed within the reach of all classes in the Danish states. Besides numerous private and charitable institutions for this purpose, every parish is provided with one or two schools, where children are instructed in the reading and writing of their native language, and in arithmetic. The schoolmasters have, in general, a salary of about £12 per annum, a house, and a few other advantages. And at Copenhagen, and some other places, institutions are established for the purpose of forming teachers to fill the parish schools. In these institutions they are instructed in the necessary branches of education; and, at the same time, in a school which is attached to the seminary, they exercise the art of teaching under the eyes of the professors. They are furnished by the institution with lodging, fire, and candles. In applications for admission, the sons of schoolmasters are preferred. Besides the ordinary parish schools, there are various Latin schools in the different parts of the country, maintained at the expence of the crown: 19 in Denmark Proper; 4 in Norway; 11 in Sleswick; 16 in Holstein; and 2 in Iceland. In these schools, besides Latin, are taught history, geography, Greek, and Hebrew. The salaries of the teachers vary from £60 to £200.

Parish schools.

Latin schools.

The constitution of these seminaries, founded in an unenlightened age, requires many corrections. At Odensee is a college, or gymnasium, with four professors, who teach rhetoric, theology, philosophy, mathematics, and Greek and Hebrew. The famous academy of Soroe is now fallen into complete decay. The great public seminary of education in Denmark is the university of Copenhagen, which was founded in 1479 by Christian the First, and has been augmented and amply endowed by his successors. It possesses a very considerable fund, and the professors have liberal salaries. It has a library of about 60,000 volumes—a chemical laboratory—a cabinet of natural history—a botanic garden—and an anatomical theatre. The number of the students is generally about 700, who come not only from Denmark, but also from Norway and Iceland. There is another university in the city of Kiel, in Holstein, also well endowed, having twenty ordinary professors, with salaries of about 1500 rix dollars. This university has likewise a good library—a botanic garden—an observatory—and an anatomical theatre. The number of students is, at an average, about 200.

College of Odensee.

University of Copenhagen.

Of Kiel.

The Royal Academy of Sciences was founded in 1742, and owes its institution to the zeal of six literati, whom Christian the Sixth ordered to arrange his cabinet of medals. These persons occasionally meeting for that purpose, extended their designs, associated others who were eminent in several branches of science, and, forming a literary society, employed themselves in examining and explaining the history and antiquities of their country. At the recommendation of the count of Holstein, Christian took it under his protection, called it the Royal Academy of Sciences, endowed it with a fund, and ordered the members to join to their other pursuits natural history, physics, and mathematics. In consequence of the royal favour, the members engaged with fresh zeal in their pursuits; and the academy published many volumes of transactions in the Danish language, some of which have been translated into Latin. About the same period, a society for the improvement of northern history and languages was instituted by a few persons, at the head of whom was Langebek, since greatly distinguished for his historical publications. Many new members being admitted, Christian the

Literary institutions.

Royal academy of Sciences.

Statistics. Sixth, with his usual zeal for letters, constituted it, in 1746, a Royal Society. It has proved itself not unworthy the royal protection, having given to the world several publications which tend to throw considerable light on the annals of Denmark. The Academy of the Fine Arts was founded in 1754 by Frederic the Fifth. This academy consists of a president, a director, eight professors of painting, sculpture, and architecture, and four teachers of design, and a secretary. The pupils will sometimes amount to 800, and are all taught gratis. A Commission of Antiquities has also been established, which has published two volumes of its Transactions, under the title of *Antiquarian Annals, published by the Royal Society in Copenhagen for the Preservation of Antiquities;* one of which appeared in 1812, and the other in 1813.

Literature, &c. The literature of Denmark cannot aspire to much antiquity, having followed, as usual in other European countries, the introduction of Christianity. In the 12th century flourished the historian Saxo Grammaticus, whose History of Denmark abounds, indeed, with fable, but whose style is remarkably classical for that age. His cotemporary, or predecessor, Sveno, is more authentic and concise, and is esteemed the father of Danish history. In astronomy, Denmark has to boast of Tycho Brahe, one of the most celebrated names in that department of science. The Danish literati have particularly turned their researches to the history and antiquities of the north. Among those who have greatly distinguished themselves in this branch of learning, must be mentioned the names of Maersius, Holberg, Olaus Wormius, Pontopidan; and more lately, those of Langebek, Schoening, and Suhm. The Danes have been by no means deficient in the study of natural history. The *Flora Danica*, begun by Oeder under the royal auspices, in 1762, and afterwards conducted by Muller, is one of the most magnificent and valuable works of the kind. And the collection of rare shells, in two volumes folio, engraved and coloured by Regenfuss, at the king's expence, is the most splendid work of that description ever produced by any nation. In 1761, Frederic the Fifth, with a view of extending the bounds of knowledge, sent four persons, eminently versed in different branches of science, to Arabia; of which curious and interesting journey, Niebuhr, the only survivor, has published a much esteemed account.

CHAP. XII.

Language, Manners, Customs, &c.

Language. The language of Denmark is a dialect of the Teutonic, but French and High Dutch are spoken at court; and the English is also very generally learned amongst the higher classes. In their persons, the Danes are, in general, tall and robust; their features and complexion are good; and their hair of a flaxen, yellow, or red colour. The women are said to be rather clumsy in their shape, and awkward in their dress. The food of the lower classes consists chiefly of oat cakes, rye bread, fish, cheese, &c. But the tables of persons of condition are plentifully covered with every luxury. Drunkenness and excess are the vices to which the Danes are most addicted. Manners, &c. The character and manners of the inhabitants of every country depend much on the nature of the government; and those of the Danes have undergone successive changes, corresponding with the changes in their political situation. Before the government was made hereditary and absolute, the nobility and gentry lived in great splendour and affluence. Their country-seats were magnificent, and their hospitality unbounded; and when the states were annually assembled, they met their sovereign with retinues as numerous and brilliant as his own. Now they are fallen from that height of insolence and power; their condition is low, and they diminish daily in number and credit. Molesworth affirms, that in his time their estates scarcely paid the taxes imposed on them, which obliged them to grind the faces of their poor tenants, to get an overplus for their own subsistence. The common people, he says, are a poor mean-spirited dastardly race, totally degenerated from the warlike disposition of their ancestors; equally addicted to fraud themselves, and suspicious of it in others. Lord Molesworth, it is probable, has taken the most unfavourable view of the Danish character; but there is no doubt it has been altered much for the worse by the revolution, which converted their free government into a despotic monarchy. The ameliorations, however, which their patriotic sovereigns have for a long time past been gradually introducing, have produced a sensible improvement on the Danish character. Extravagance of every kind is still a very general disposition of the Danes. The peasantry are poor and dirty; but the superior ranks differ little from those of the same class in the other countries of Europe. See *Mod. Univ. Hist.* vol. xxxii. Denys. DENYS, St, *Sanctus Dionysius,* an ancient town of France, in the department of the Seine, is situated on the banks of the Crould, on an agreeable and fertile plain near the Seine. This town rose into notice, in consequence of the celebrated abbey of Benedictines of the congregation of St Maur, which was founded over the tomb, and in honour of St Denys and his companions, by King Clothar, A. D. 600. This abbey was successively improved by the kings Dagobert, Pepin, Charlemagne, and Charles the Bald. The church, which was completed A. D. 1181, is a fine Gothic building, of the finest freestone, and covered with lead, and is greatly admired for the lightness of its architecture. Its treasury was, under the dynasty of the Bourbons, considered the richest in Christendom. This abbey has been the burying-place of the kings of France and of the royal family; and it contained, before the revolution, many splendid monuments; among which was that of Charles V. and his Queen, Charles VIII. Louis XII. and his Queen, Francis I. and his family, Henry II. with his wife and children; Bertrand du Guesclin, constable of France; and the Marshal Turenne, whose ashes Louis XIV. wished to be mixed with those of kings. These splendid monuments, however, were in a great measure destroyed and carried away during the anti-regal fanaticism which prevailed during the French revolution. The ashes and bones of the kings were impiously scattered in the air; and a few fragments of the monuments which covered them, were preserved by the antiquarian zeal of M. le Noir, and are now in the National Museum. The monastery is a very fine modern edifice.

Since the Emperor Napoleon ascended the French throne, he has endeavoured to expiate the sins of the revolutionists, by repairing and embellishing the church. Two of the windows have been ornamented with the finest painted glass. Between two expiatory altars in the nave, one for the Merovingian, and another for the Carlovingian race, is a column which is to be hung with the portraits of the six French monarchs who were emperors. An expiatory altar for the third dynasty of the Capets is placed on the left side of the nave. The principal altar is placed in the centre; and the stair cases which lead to the choirs are of marble. Napoleon has also restored the vaults which contained the royal monuments, and has defended it with a massy gate of gilt brass.

A number of curiosities, both sacred and profane, are preserved in this town; but particularly the vase of Oriental agate, which represents a feast celebrated in honour of Bacchus, and which is reckoned one of the finest, as well as one of the most valuable articles of the kind. Several manufactures are carried on in St Denys, particularly refining of sugar, and a manufactory of Indian stuffs. Not far from the town, on the road to Epinay, is an extensive bleaching establishment. Population 4425. Distance north of Paris, 6 miles. See Reichard's *Guide des Voyageurs en France*, Weimar, 1810; and *Coup d' oeil Historique sur la ville et l'eglise de St Denis avec le Plan*, Paris 1802. (*w*)

DEPTFORD, a large and populous town of England, in the neighbourhood of London, and in the county of Kent. It is situated on the banks of the Thames, at the mouth of the small river Ravensbourne, which is here navigable for lighters and small craft, and which is crossed by a good stone bridge. The town, which is divided into the Upper and the Lower town, is very irregularly built, but contains many good modern houses and shops. The principal edifices in the town are the two churches and the naval buildings, to which it owes all its importance. The church of St Nicholas consists of a nave, chancel, and aisles, and has an embattled tower of stone and flint, much older than the body of the church itself. The old church had been enlarged about the year 1630, and the body of the present fabric was rebuilt in 1697. It contains numerous monuments, the principal of which are those of Captain Fenton, Henry Roger Boyle, George Shelvocke, Esq. Sir Richard Browne, Mr John Benbow, &c. The church of St Paul is a handsome stone building, which was erected before the year 1730. It has a good spire at the west end, and consists of a nave, chancel, and aisles. The roof is sustained by Corinthian columns, and the inside is neatly fitted up. The principal monuments are erected to Admiral Sayer, and Matthew Finch, Esq. The rectory house is a handsome building. The Old Hospital, which was rebuilt in 1788, contains 25 apartments. The Trinity Hospital, which was erected in 1672, forms a spacious quadrangle, containing fifty-six apartments. A statue of Captain Richard Maples, who, in 1680, bequeathed L.1300 to the hospital, stands in the centre of the quadrangle. The pensioners in both these hospitals, are old sailors and masters of ships, and their widows. There are also in Deptford several valuable establishments for the education of the poor.

The principal naval buildings are, the royal dock or king's yard, the victualling office, and the private docks. The king's yard includes about thirty-one acres, which are covered with various buildings, and it contains a double and a single wet dock, three slips for men of war, a basin, two mast-ponds, a model loft, mast houses, a smith's shop, with nearly 20 forges for the manufacture of anchors. The old store-house is a quadrangular pile of building. The range on the north side bears the date of 1513, and those on the other sides have been built at different times, a double front having been added towards the north in 1721. Some years ago another store-house was built parallel to the old one, and a range of smaller store-houses were erected in 1780. The victualling office, or red house, has been erected at different times since the year 1749, and consists of houses for the principal and inferior offices, granaries, bake-houses, slaughtering-houses, houses for curing beef, brew-house, and a wind-mill for grinding corn. A kind of earthen ware, called Deptford ware, is manufactured here to a great extent.

The following is an abstract of the population return for 1811 for the town of Deptford.

Number of inhabited houses	3,463
Number of families that occupy them	5,010
Number of houses building	97
Number of houses uninhabited	59
Families employed in agriculture	208
Families employed in trade and manufactures	3,413
Families not included in these classes	1,389
Males	9,526
Females	10,307
Total population in 1811	19,833
Total population in 1801	17,548
Increase since 1801	2,285

See Hasted's *History of Kent*; and Brayley's *Beauties of England and Wales*, vol. vii. p. 456—469. (*π*)

DERBENT, Derbund, or Derbend, a city of Persia, in the province of Daghestan, of which we have already given a full account under the article Daghestan.

DERBY, a town of England, and capital of the county of the same name, is situated in a valley, extending and opening as it advances southward, into a fine and well cultivated plain. It stands on the western banks of the river Derwent, on ground a little elevated above the level of the surrounding vale; its situation is, therefore, very pleasant; and the scenery in its environs extremely beautiful.

Antiquarians do not agree in the derivation of the

Derby.

name *Derby*. Historians inform us, that during the Heptarchy the Saxons called it *Northworthig*; but of this appellation, not a trace now remains. In the time of the Danes, it was called *Dearaby*; a word, said to be compounded of two Saxon ones, signifying a habitation for deer; but this derivation is too fanciful to admit of any credit. The most probable conjecture is, that the name of the town, and that of the river *Derwent*, have the same origin; that originally it was *Derwentby*, or the town by the Derwent; and, that in process of time, this name was corrupted, or abbreviated into *Deorby* and *Derby*.

From the contiguity of Derby to the Roman city *Derventio*, now called *Little Chester*, it is supposed that it must be a place of some antiquity, and of some consequence prior to the Roman invasion; for the Romans generally fixed their stations in the vicinity of some British town. But in what age, or by what nation it was founded, it is impossible to determine.

Antiquities.

There are but few antiquities in Derby. Formerly there stood a castle near the south-east corner of the town, but there have been no remains of it in the memory of any person living. About twenty years ago, an antiquarian took some pains to search out its site. He discovered some vestiges of it, near what is called Castle-hill, in an orchard: it was guarded by the Derwent on one side, and on the other runs, at present, the London road. It is the opinion that Derby castle was built about the reign of Stephen; and that it was destroyed during the civil wars between the houses of York and Lancaster.

Religious houses.

We are informed by ancient authors, that there were six religious houses in the town of Derby; several of which were in existence at the suppression of the orders by Henry VIII. The monastery of St Helen's, belonging to the order of Austin Friars, was situated on the spot where the spar manufactory now stands, near the upper end of Bridge-gate. It was erected in the reign of Stephen, by Robert de Ferrers, second Earl of Derby. But in the reign of Henry II. the abbot and canons removed to Darley, a beautiful spot, about a mile from the town, situated on the banks of the Derwent. A priory of Dominican, or Black friars, once stood on the spot where the mansion and grounds of M. Henley, Esq. now stand, in the Friar-gate. It is thought to have been founded in very early times; and was dedicated to the blessed Virgin. On the north-west side of Nun's-green, in the meadow that was called Nun's-close, stood a priory of Benedictine nuns, dedicated to St Mary de Pratis. It was founded by the abbot of Darley, in the year 1160. Near the brook, on the north of St Jances' lane, stood a cell of Cluniac monks. It was of Saxon origin, and founded by Waltheof, a nobleman of that nation, who was beheaded by William the Conqueror in the year 1074. He dedicated it to St Jances, and presented to the Abbey of Bermondsey, in Southwark. A Mansion de Dieu, a hospital for leprous persons, was founded in Derby, as early as the reign of Henry II. There was also here, an old hospital of royal foundation, consisting of a master and several leprous brethren, dedicated to St Leonard. St Mary's was an old building in the Saxon style, situated upon the verge of the Derwent, and forming a part of the old bridge. It is thought to have been one of the six churches mentioned in Domesday-book.

Churches.

All Saints.

At present, Derby contains five churches, the principal of which, is All Saints. The tower of this church is much admired. It was built in the reign of Henry VIII. or of Mary; and is an elegant specimen of the Gothic architecture. The workmanship is of a superior kind, and reckoned excellent; it is richly ornamented, and rises to the height of 180 feet; towering above the churches and houses, it forms a beautiful and striking object from the surrounding country. Tradition says, that it was built at the expence of the bachelors and maidens of the town; but the opinion is merely conjectural. Between this tower and the body of the church, there exists an uncommon instance of architectural incongruity; for to this beautiful specimen of Gothic architecture, is added a Grecian body of the chastest proportions and most classical design. It was built from a design by Gibbs, in the years 1723-4-5. The expences of the erection were defrayed by voluntary subscriptions, which were raised and directed by Dr Hutchinson, who was then the curate. This worthy man, by indefatigable industry, raised nearly L.7000 by his own exertions in begging, and executed this masterly work without a shilling of expence to his parish. The interior of this church is large, light, and elegant; five columns on each side support the roof; the windows are large and handsome; and the symmetry and harmonious proportions of the building, have a pleasing effect. The church contains several monuments of the Cavendish family; and many persons of that illustrious house are buried here. The principal are the following: one erected to the memory of the famous Countess of Shrewsbury; another to William Earl of Devonshire; one by Rysbrack to the memory of Caroline of Besborough; and another by Nollekins, displaying the medallion and arms of her husband William Ponsonby, Earl of Besborough. The church contains a good organ, and the tower a set of good bells and chimes.

St Alkmund's.

St Alkmund's church stands at the north-east end of the town, and was erected about the middle of the eighth century. This, like All Saints, is in the gift of the corporation. The church of St Peter is situated near the southern extremity of the town, and is thought to be the same as the one mentioned in the time of king Stephen, dedicated to the same apostle. St Werburgh's is situated on the western side of the town, upon the Markeaton-brook. St Michael's stands in Queen-street. This living, is a vicarage united with St Werburgh. Besides the above mentioned churches, the Presbyterians, the Independents, the Baptists, the Quakers, the Roman Catholics, and the Methodists, have their respective places of worship in the town.

St Peter's.

St Werburgh's.

St Michael's.

Charitable institutions.

One of the most considerable charities in Derby, is the Devonshire Alms-houses, situated near All Saints. This was founded by the Countess of Shrewsbury, in the reign of Elizabeth, for eight men and four women. The rules for the observance of the inmates are, "that they are not to marry or get drunk, without expulsion; to lie one night out incurs a forfeiture of four-pence; if absent one day, six-pence; to miss prayers at All Saints, two-pence; to strike a blow, one shilling; and if three blows, a discharge." In the Bridge-gate there are eight alms-houses for an equal number of the poor and aged of both sexes. Another alms-house, for the widows of clergymen, is situated at the top of the Friar-gate. The inmates, who are five, receive L.17 a year each. For the education of the children of the poor, the free-school in St Peter's church-yard was originally intended, and has endowments to support two masters; but the only schools where the really poor are now admitted, are the Lancastrian and Bellian schools, which have lately been established by subscriptions raised in the town and neighbourhood.

The principal buildings in Derby are, a county and

Derby.

Coun-y hall. town-hall, a county gaol, an elegant assembly-room, a theatre, and an infirmary. The county-hall was erected in 1660, and is a large heavy building of stone. The town-hall is a handsome structure of brick, built by the corporation about the year 1731. The county gaol, is situated on the western side of the town, near the upper end of Friar-gate. It was erected in the year 1756, at the expence of the county, aided by a donation of L.400 presented by the Duke of Devonshire. It is a solid plain building of brick, well adapted for the purpose of its destination. The assembly-room is an elegant building of stone, situated in the market-place. Its erection was completed in 1774. The theatre is a neat building of brick, with an interior plain and commodious. It was erected by a private individual, in the year 1773.

Gaol. Assembly-room. Theatre.

General infirmary. The erection of the Derbyshire general infirmary,* was commenced in the spring of the year 1805, and the building was completed for the reception of patients on the 4th June, 1810.

The site of the building is at a short distance from the town of Derby, immediately adjoining the London road, from which it forms a very good object, greatly improving that entrance into the town.

The ground plan is a square, the side of which is about 100 feet. The sides are not in the same straight line. If we suppose each side divided into three equal portions, the middle portion of each side stands within the other portions about eight feet, so that the walls of the latter are distant eighty-four feet on each side, and the walls of the projecting portions one hundred feet. The floor of the basement story is three feet below the surface of the land on which the building is erected, and the second story eight feet and a half above the same. The entrance into the latter is by a right and left flight of steps terminating in a portico, after the model of the Parthenon on the Acropolis at Athens. This entrance is into a spacious hall, not less than 34 feet square. The apartments on this floor are, the board-room on the left side of the entrance, and the matron's room on the right. On the left side of the hall are the apothecary's rooms, the apothecary's shop, and the out-patients' room; the latter is also employed as the chapel. On the right side of the hall, are the physicians and surgeons rooms, and the porter's rooms.

From the centre of the hall, and facing the entrance, the stair case commences. It first rises to a landing, which is joined to the opposite wall; it then divides into a right and left flight of steps, which occupy one side of the hall, and lead each way to a gallery or balcony, projecting six feet within the hall, on the other three sides. From the centre of the front balcony, is the entrance into the operating room, which is directly over the entrance below. It is well lighted, and every way fitted for its intended purpose.

All the other rooms on the right and left are divided into wards of various sizes. The left side is for the males, and the right side for the females, each apartment on one side being precisely similar to that on the other.

Those wards nearest to the operating room are small, each containing one bed only. Others, adjacent, contain two beds. In the centre of these small wards is a small room, called the nurse's scullery. It contains a small stove and other conveniences. Adjacent to this is the nurse's bed-room. This part, which is on each side the same, is destined for acute diseases, in which the stilness and privacy afforded by this arrangement, are of great importance. The rest of the wards are larger, and contain more beds, as the cases require. On the same floor, on each side, is a spacious room, one for the males, the other for the females. These are called convalescent rooms. They are for the reception of all the patients who are not immediately confined to their bedrooms. This constitutes the third and last story.

Derby.

General infirmary.

The hall is lighted by a skylight, which forms a dome in the centre of the building. The rest of the roof, which covers the rooms, slopes towards the cornice on one side, and towards the dome on the other, the ridge being over the middle of the range of rooms on each side.

The dome is made of cast iron, put together in segments. On the centre is placed a round pedestal of stone, upon which stands a colossal figure of Esculapius, modelled in clay, by a Mr Coffee of this place.

A portion of the back part of the house, from the basement story upwards, is kept completely distinct from the rest, constituting fever wards. This part has in no respect whatever any communication with the rest of the house; and has, hitherto, been as successful in preventing the communication of contagion, as if it were at a greater distance.

The basement story contains the kitchen, the scullery, the wash-house, and the laundry. It has a separate entrance from the front, under the portico of the story above, on each side of which is a public bath, one being kept at the heat of Buxton water, and the other of that of Matlock. There are five spacious baths, elegantly fitted up, which bring a handsome income to the charity. They are heated by steam, which is brought in pipes from the boiler of a steam engine of one horse power, which is employed to pump water from a well below into a cistern at the top of the house, and to perform a variety of other offices connected with the economy of the establishment. The kitchen is a pattern for neatness and convenience. The fire place in it is not larger than to keep the room comfortably warm, and is not employed for any culinary purpose. The baking and roasting is performed by an oven on very superior principles, invented by Mr W. Strutt of this place. It is so contrived, that the greatest possible proportion of the heat is applied to the body contained in it, while no part of it comes into the room. The principal advantage, however, of this invention, consists in the heat being applied equally on every side of the substance at the same time, so that the door of the oven is never opened for the purpose of turning what may be contained in it.

Near to the roaster is a steaming apparatus, invented also by Mr Strutt, and applicable to all culinary purposes. A recess is made in the wall similar to that for stoves in common use. The bottom of this recess is formed by a flat piece of cast metal, capable of holding the number of dishes intended to be steamed. Round this, is a groove filled to a certain height with water. The whole is covered by an inverted vessel of tinned copper, in the form of a dish cover, the edges of which

* As we consider the Infirmary of Derby to be one of the most complete establishments of the kind in Europe, we have deviated from our general plan, in giving a very minute account of a building which reflects equal honour upon the liberality of the town, and the skill of the gentlemen under whose superintendence it was completed. Ed.

Derby.

General infirmary.

drop into the groove above mentioned. The steam is let in at the middle of the table or plate, and the condensed water runs off at an opening in the groove.

The boilers, in which the soup and milk pottage are made, have no fire places, being all heated with steam. The scullery is supplied with hot water from a large vessel, which, by the agency of steam, is kept always hot, and by another contrivance always full.

The most important part of this establishment is, the means of keeping that part of the house destined for the patients, at an uniform temperature throughout the year. This is effected by a current of warm air passing through the rooms in winter, and a supply of cool air during the hot months of the summer, accomplishing by the same means perfect ventilation, which is so essential to places of this description.

The air which passes through the rooms at all times, enters through a subterraneous channel, the opening to which from the atmosphere, is distant about 100 yards from the building. This channel, from its depth below the surface, is so near the mean temperature of the earth, that the air of winter is partially warmed, whilst that of summer is considerably cooled. In the greatest heat of summer at this place, the temperature of the air is lowered in its passage as much as 20° of Fahrenheit's scale. In winter, the same air, after it escapes from the channel, passes through a stove on very superior principles, the invention of the ingenious philosopher before mentioned. The fire is made to act upon the interior of an inverted dome-shaped vessel, constructed of iron, while cold air is plentifully supplied on the outside to carry off the heat given to it by the fire. This is effected in so complete a manner, that the largest fire which could be made under the dome would not heat it to redness, provided that the communication of the air to the room in which the stove is placed, remained uninterrupted.

The writer of this article is, at present, preparing a work for the public, in which, all the inventions connected with this establishment will be particularly described. It may be observed, in addition to the above, that in this infirmary, the wash-house and laundry are so contrived, that much manual labour is saved, and the utmost cleanliness insured. The principal part of the washing is performed by a machine which is turned by the steam engine. The drying is effected, in bad weather, by a stove, on principles similar to that used for warming the rooms. This also serves at any time for airing linen and beds.

In most infirmaries and hospitals, the construction of the water-closets in common use, is so extremely bad, as to be the occasion of great and deserved complaint. This inconvenience is entirely obviated here. It would be improper to enter into particulars of the construction of them in this place, but it may be stated generally, that they are so contrived, that the oftener they are used the less smell will be perceived. Every time the closet is entered, the whole of its contaminated air is changed for fresh air, and every source of nuisance at the same time washed away, independent of any care of the person who uses it.

Ordnance depot.

Not far from the Infirmary, and about the same distance from the town, is an ordnance depôt, erected by the Board of Ordnance in 1803, according to a plan by Mr Wyatt. It consists of an armory in the centre, calculated to contain 15,000 stand of arms. Above this is a room of the same proportions, containing accoutrements for the use of the army. On the north and south sides, are two magazines, capable of containing 1200 barrels of ammunition. Four dwellings are situated in the angles of the exterior wall; two of which are barracks, and the other two are the residences of officers in the civil department.

Trade.

Concerning the trade of Derby, old authors are nearly silent. It is thought, that the oldest carried on in the town was that of a dyer. Wool and malt were also among the articles of its early commerce. Trade was confined to these articles, until the commencement of the eighteenth century, when the stocking-frame machine was introduced into the town. This was a considerable addition to the commercial interests of the place; but what gave it a pre-eminence in this respect, was the erection of the first mill in this country for the manufacture of silk.

Silk mill.

This silk mill, the first and largest of the kind ever built in England, stands upon an island in the river Derwent, adjoining the town. At the commencement of the last century, a person of the name of Crotchet, erected a small mill near the present works, with the intention of introducing the Italian method of spinning into this country. About the year 1715, a similar plan was in the contemplation of a mechanic and draughtsman, named John Lombe, who travelled into Italy, to procure drawings, and models of the machines necessary for the undertaking. After remaining some time in that country, and gaining as much information as the jealousy and precautions of the merchants of Italy would allow, he returned with two natives, accustomed to the manufacture, into this country; and fixed upon Derby as a proper place to establish his works. He agreed with the corporation, for an island, or rather swamp, in the river 500 feet long, and fifty-two wide, at a rent of about eight pounds yearly. Here he established his silk mill: and in 1718 procured a patent to enable him to secure the profits for fourteen years. But Lombe did not live much longer; for the Italians, exasperated at the injury done to their trade, by its introduction into England, sent an artful woman over, who associated with the parties in the character of a friend; and having gained over one of the natives who had originally accompanied Mr Lombe, administered a poison to him, of which, it is said, he ultimately died. His death, however, did not prove fatal to his patriotic scheme; for his brother, and afterwards his cousin, carried on the business with energy, and employed more than 300 people. A little before the expiration of the patent, Sir Thomas Lombe petitioned for a renewal of it; but this was refused, and instead of it, £14,000 was granted him, on condition that he should suffer a complete model of the works to be taken: this was accordingly done, and afterwards deposited in the town for public inspection. The property now wholly belongs to the corporation. The present occupier employs about 240 hands.

This extensive mill stands upon huge piles of oak, double planked, and covered with stone work, on which are turned thirteen stone arches, which sustain the walls. Its length is 110 feet, its breadth 39; and its height 55 feet. It contains five stories: in the three upper, are the Italian winding engines, which are placed in a regular manner across the apartments, and furnished with many thousand swifts and spindles, and engines for working them. In the two lower rooms, are the spinning and twist mills, which are all of a circular form, and are turned by upright shafts passing through their centres, and communicating with shafts

Silk mill.

from the water-wheel. The spinning mills are eight in number, and give motion to upwards of 25,000 reel bobbins, and nearly 3000 star-wheels belonging to the reels. Each of the four twist mills, contains four rounds of spindles, about 389 of which are connected with each mill, as well as numerous reels, bobbins, star-wheels, &c. The whole of this elaborate machine, though distributed through so many apartments, is put in motion by a single water-wheel, twenty-three feet in diameter, situated on the west side of the building.

All the operations, from winding the raw silk to organizing or preparing it for the weavers, are performed here. The raw silk is chiefly brought in skains or hanks from China and Piedmont. The skain is first placed on a hexagonal wheel or swift, and the filaments which compose it are regularly wound off upon a small cylindrical block of wood, or bobbin. To wind a single skain, is the work of five or six days, though the machine be kept in motion for ten hours daily; so astonishingly fine are the filaments of which it is formed. The silk thus wound upon the bobbins, is afterwards twisted by other parts of the machinery, and is then sent to the doublers. Here four, seven, or ten threads are united into one, according to the uses for which it is designed: the fine kind going to the stocking-weavers; the others to different manufactures.

Besides this mill, there are several other works of a similar nature, now established in Derby; but of very superior machinery. Indeed, the old mill proves, at how low an ebb mechanical knowledge was in England as well as Italy, when that was constructed. The situation of Derby on the banks of the Derwent, renders it favourable for carrying on manufactures which require the aid of water. The mills established by the Messrs Strutts, for the manufacture of silk and cotton, are particularly ingenious in their machinery; and the facility attained by them in working the several articles of manufacture, has contributed to the extension of these branches of business, in a very eminent degree.

Cotton mills.

Porcelain manufactory.

The porcelain manufactory was established about the year 1750, by a gentleman of the name of Duesbury. Since his decease, very great improvements have been made, in the preparation of the materials, and in the appearance of the ware. It is thought to equal, in fineness of texture, the French and Saxon, while it far surpasses them in workmanship and elegance. The paintings are, in general, rich and well executed; and the gilding and burnishing very beautiful. The manufactory employs about 200 hands.

Another considerable manufactory carried on in this town, is that of gypsum, fluor-spar, and marble. These are formed into a great variety of very beautiful ornaments; and the Derbyshire marble is well known in almost every part of the kingdom, and much admired. The machinery which Messrs Brown and Son have invented for sawing and polishing this marble is exceedingly ingenious, and worthy of notice. The manufacture of stockings is carried on to a very great extent in Derby: it was here the rib-stocking frame was invented, and first worked. The business of the lapidary and jeweller is also of some magnitude here; and articles of the paste kind are executed with great elegance and ingenuity. The other manufactures, are bleaching, slitting and rolling iron, tin-plate, lead pipes, red and white lead works, and a shot tower.

Improvements.

Derby has rapidly increased within the last few years, in size and population; and is still increasing in wealth and commerce. Fresh ground is continually broken up, and houses are erected in every direction. Among the modern improvements in the place, may be mentioned, the lighting and paving the streets, the erection of several new bridges over the brook that runs through the town; and an elegant bridge of three arches, thrown over the Derwent, on the north-east side of the town.

Philosophical societies.

Dr Darwin, though not born, yet spent the last one-and-twenty years of his life at Derby; and by his residence there, diffused a taste for literature and science, which still continues to be one of the principal characteristics of the place. He was the patron and founder of an establishment known by the name of the *Derby Philosophical Society*, the objects of which were the promotion of scientific knowledge by the occasional meetings and convocation of its members, and by the circulation of books. The date of the formation of this institution was the year 1788, the first meeting being held at Dr Darwin's own house, when he was chosen president, and read to his associates a most appropriate and excellent introductory essay on the progress of human knowledge, which, it is to be regretted, has never met the public eye. He retained the chair of this society till his decease, since which time it has been ably occupied by his intimate friend, and disciple, Mr Strutt, of whose merits some mention will be found in another part of this article, and in some other parts of our work. The Philosophical Society still boasts a considerable number of members, and is in possession of an extensive and valuable library; but its utility, as a scientific body, has of late years, in a certain degree, declined. The want of some compulsory law, by which questions for conversation should be *regularly* furnished, has robbed the meetings of part of the interest which they originally possessed; and as a few of the more active members were anxious to enjoy all the advantages which such an association was capable of supplying, the idea of a new establishment was thence excited, in which subjects for discussion might be more strictly and constantly furnished. To have accomplished this under the auspices of the parent society was impossible, from the known unwillingness on the part of the majority of the members then composing it to consent to such a restraint. This gave rise to the foundation of a new and very flourishing institution, which made its appearance in the year 1808, under the title of the *Derby Literary and Philosophical Society*. The objects of this association, as stated in its printed rules, are "the pursuit of literary and scientific inquiries, and the improvement of its members in the power of gaining, and of communicating, knowledge." The means by which these objects are attempted to be accomplished, is by the production and discussion of papers, or essays, which may be written on any subject connected with literature or science, excluding only the *practical* departments of medicine and surgery, party politics and religion. It is a fundamental law of this society, that each member shall furnish an essay in his turn, and no instance has hitherto occurred in which this rule has been violated. The meetings are held monthly from September to April inclusively, one paper being read, and another discussed, on each evening. In addition to the above, the society had also adopted the plan of delivering annually a public course of lectures, the profits of which are applied to the purchase of philosophical apparatus. These have been attended with the most complete success, and the members who have employed their talents in this way have acquitted

Derbyshire.

themselves with great credit. Besides the two societies already mentioned, there are not less than eight or ten others, in this small town, formed for the circulation of books, one of which is confined to the purchase of French works exclusively.

Derby has weekly markets on a Wednesday and Friday, and seven annual fairs, which are generally very numerously attended. It is 126 miles north north-west of London, and is situated in Long. 1° 25′ W. and Lat. 52° 58′ N.

The following is an abstract of the population-return for 1811:

Inhabited houses	2,644
Families that occupy them	2,924
Families employed in trade and manufactures	2,382
Ditto in agriculture	95
Males	5,978
Females	7,065
Total population in 1811	13,043

See *Hatton and Davies' Histories of Derby.* (D. P. D.)

DERBYSHIRE, a midland county of England, situated about the centre of the kingdom; being at an equal distance from the German Ocean on the east, and St George's Channel on the west; and on the north and south, the extremities of Northumberland and Hants are nearly alike remote. On the north, it is bounded by Yorkshire, and a part of Cheshire, which is separated from it by the river Etherow; on the south, by a part of Leicestershire; on the east, by the county of Nottingham and another part of Leicestershire; and on the west, it is divided from Staffordshire and Cheshire by the Trent, the Dove, and the Goyt. It is included between the parallels of 52° 38′ and 53° 27′ North Lat. and between 1° 13′ and 2° 3′ 30″ West Long. It is the twentieth county in the order of magnitudes, and the nineteenth in the order of population.

Ancient state.

In the time of the Britons, Derbyshire is found included in the number of counties that made up the kingdom of the *Coritani;* but the Romans, when they gained possession of the island, made a new division of it, and Derbyshire made a part of *Flavia Cæsariensis.* Under the heptarchy, Derbyshire was included in the kingdom of *Mercia.* The figure of the county is so irregular, and its outlines so variable, that it can hardly be said to bear a resemblance to any determinate figure. It approaches nearer to that of a triangle than any other; but its numerous curves and projections make the resemblance more imaginary than real. Its greatest length, from north to south, is about 56 miles, and its breadth, at the northern extremity, 33; but from thence it gradually diminishes, so that at its southern extremity it narrows almost to a point. Its circumference is about 204 miles, containing about 972 square miles, or 622,080 statute acres, of which above 500,000 are cultivated, arable, and pasture, whilst the remainder consists chiefly of bleak mountainous regions, heaths, and open commons.

Civil division.

The civil division of Derbyshire is into six hundreds; the High Peak hundred, Scarsdale hundred, Wirksworth Wapentake Appletree hundred, Molleston hundred, and Reppington hundred. These are subdivided into parishes, (which are about 116) townships, and hamlets. The county contains 11 market towns; and the population (1811) amounted to 185,487, there being then 35,658 houses inhabited by 37,440 families. The county of Derby sends two members to parliament; a privilege which it enjoyed as early as the reign of Edward I. The assizes are held at Derby in the spring and autumn, and three of the quarter sessions are also held there, the other at the town of Chesterfield. With respect to the common judicature, Derbyshire is included in the midland circuit.

Ecclesiastical state.

In ecclesiastical concerns, Derbyshire forms a part of the diocese of Lichfield and Coventry, and is divided into six deaneries, High Peak, Ashbourn, Castillar, Chesterfield, Derby, and Reppington.

General aspect.

There is no other county in England which presents such a variety of scenery as Derbyshire; the northern and southern parts exhibiting such a striking difference and contrast in geographical features. The former abounds with hill and dale; and often the scenery is romantic and sublime. The country gradually rises for about 15 miles northward, and then more abruptly, and afterwards begins to assume that mountainous appearance, which it continues to possess to its extremity. A chain of hills arises, which extends to the borders of Scotland. They are at first of small elevation; but being in their progress piled on one another, they form very elevated ground in the tract called the High Peak. The most considerable, however, in height, are Axe Edge, 2100 feet higher than the level of Derby, and Kindu Scout, 1000 feet above the level of Buxton. The southern part of Derbyshire is a pleasant, fertile country, not distinguished in its appearance from the other midland counties. The banks of the Trent is a range of low meadows, for the most part well cultivated, but presenting no variety of scenery.

Rivers.

Like all other hilly countries, Derbyshire abounds in rivers. The principal are the Trent, the Derwent, the Dove, the Errewash, the Wye, and the Rother. The most considerable rivulets are the Bootle, the Amber, the Morledge, the Ecclesburn, the Bradford, and Lathkil, the Noe, the Ashop, the Schoo, the Dane, and the Goyte. This country also is not deficient in the advantages of navigable canals.

Canals.

The first that was opened was the Grand Trunk canal, leading from the river Trent to Wilden Ferry in Derbyshire. This was planned by Mr Brindley, about the year 1766. The Chesterfield canal, completed in 1776, cut from that place to Stockwith near Gainsborough, where it enters the Trent. The Langley Bridge, or Errewash canal, the act for which was obtained in 1777, is navigable from Langley bridge to the Trent. The Peak Forest, proceeding from the Ashton Under Line canal to the northern parts of Derbyshire, was finished in the year 1800. Cromford canal begins at Cromford, and joins the Errewash at Langley bridge. The Ashby-de-la-zouch was completed in 1799, and the Derby canal in 1794. These six are the only canals hitherto formed in Derbyshire.

Climate.

The atmosphere and climate of Derbyshire vary much in its different districts. From its northern situation, even the southern part of the county is colder, and more frequently visited by rains than many of the more central counties of England. Owing to the great elevation of the northern part, it is found much colder than the southern. Some grain will not ripen at all in the Peak. It is not uncommon to see oats out and uncut in October and even November. The winters, in general, are very severe; and the frost continues so long in the ground, that it cannot be broken up until the season is far advanced: the consequence is, that the corn has seldom sufficient time to ripen, and is cut down and left to wither in the sun and to be dried by

Derbyshire.

the air. It has been supposed, that the mountains of the Peak of Derbyshire attracted the clouds, and that this part of the county was distinguished by frequent and heavy rains; but Mr Farey, in his late survey, doubts the accuracy of this opinion. From the rain-gauge kept in the gardens of Chatsworth, it appears, that the total depth of water fallen from the year 1763 to 1810 inclusive, including melted snow, was not more than 119 feet, giving an yearly average of 28,411 inches; and the average number of the days of rain in each month, was nearly as follows: January 9 days, February 10, March 8, April 9, May 9, June 9, July 11, August 10, September 11, October 12, November 11, December 11 days.

Soil and agriculture.

The soil of Derbyshire is almost as various as its appearance. In the northern parts of the county very extensive peat bogs exist; the soil in these parts consists chiefly of ligneous particles, being roots of decayed vegetables, mixed with the argillaceous vegetables earth or sand, and a coaly substance derived from decayed vegetable matter. The surface presents nothing but a barren bleak moss, thinly clothed with heath. But in many parts of the Peak there is to be found what the natives call a *corn loam;* this consists of virgin earth impregnated with nitre. Where this corn loam is in sufficient quantity, and meets with a stratum of marl or clay, it forms a desirable field for cultivation; but these spots are overbalanced by the vast tracts of barren hills and mountains, whose sides present very little soil, being chiefly composed of rocks. When the limestone forms the mountain, the soil, though scanty, is productive of the finer grasses, which form good pasturage for sheep.

The most common soil in the southern parts is a reddish clay or marl. This soil, which has little or no stone beneath the surface, is also found to prevail through the middle part of the extensive tract of limestone, which lies on the north-west side of the county; and consists of much calcareous earth, which readily effervesces with acids. Some parts of the southern districts are interspersed with small beds, and strata of sand, gravel, and other alluvial soils. The large tract of the county that produces coal, is covered with a clay of different colours. This kind of soil is also found in some parts, where the grit-stone is to be met with; but there it is of a black colour, and frequently of a bituminous quality. That on the north-east side of the county, where the limestone prevails, is of a brown colour and loose texture. The soil on the banks of the rivers and in the vallies is different from that of the adjacent parts, and evidently has been altered by the depositions from the frequent inundations.

Owing to the barrenness of the soil and the coldness of the climate, there is but little corn grown in the northern parts; and the attention of the farmers is chiefly turned to grazing and breeding cattle. But as we approach the southern extremity, tillage becomes more frequent; and on the eastern side of the country it chiefly prevails. The midland tracts have a mixture of pasture and arable land. About the town of Derby, all kinds of grain are cultivated; and the produce is, in general, very abundant. The course of tillage generally pursued is, fallow, wheat, barley, beans, or peas. Extensive crops of turnips and cabbage also are raised; and the cultivation of artificial grasses seems more and more attended to; indeed the whole agricultural system of the county is in a state of progressive improvement. But an uncommon species of culture, in which about 200 acres of this county are employed, is that of chamomile (*Anthemis nobilis.*) Slips from old roots are planted out about the end of March on a loamy soil, and the flowers are gathered in September. The yearly produce varies from 2 cwt. to 6 cwt. and the price per cwt. from 40s. to L.9.

Great attention has been paid, of late years, by the Derbyshire gentlemen, to improve the breed of their cows. The cows are, in general, horned, large, and handsome, yielding upon an average ten quarts of milk a day; and in good grass fatten very soon. They are most commonly speckled, with large and well turned horns, though of late the short horned Lancashire breed has been introduced and preferred by some. The primary object of the Derbyshire farmer is cheese-making, of which upwards of 2000 tons are annually sent to the London market. The Derbyshire cheese is of a good quality, generally mild, and in taste, though not in richness, resembling the Gloucestershire. Derbyshire is not famed for good butter.

Nature seems to have adapted the horses of this country to the different regions in which she designed them to labour. In the northern districts, the breed is small, light, agile, hard, able to undergo great fatigue, and capable of subsisting upon scanty fare; in the southern parts they are in general of a strong, heavy, and large size. The sheep also of Derbyshire are small in the north and large in the south.

Mineralogy.

Concerning the geology and mineralogy of the county, it may be expected that some remarks should be supplied. Our observations here, however, must be necessarily confined, as the principal facts and phenomena presented in the survey of the rocks and minerals of this district, will be selected in illustration of the articles devoted to the sciences to which they respectively belong. There are few, if any, parts of the kingdom, perhaps, more interesting in these accounts than the present. The influence of that powerful agent by which the surface of our globe has been so violently disturbed, is no where exhibited under circumstances more various, or instructive; neither, if we estimate its mineral products by the abundance of those which it furnishes to the necessities and comforts of civilized life, is there any portion of these islands with higher claims to our consideration; lead, iron, coal, and lime, have, from the plenty in which they have been yielded, long given it an important place in the history of the arts; and its supplies of zinc and copper, particularly of the former, are by no means inconsiderable. In the *variety* of its minerals, too, Derbyshire is not without some boast; and a few of the specimens of our cabinets, especially the elastic bitumen, or mineral pitch, which is found near Castleton, it contributes to the exclusion of every other part of the world. The whole of its rocks belong to those two classes to which geologists have attached the names of *alluvial* and *secondary.* It has been conjectured by Professor Jameson, and, indeed, by Brochant, that the limestones and amygdaloids, which form such conspicuous features in the county, are formations, which, in the Wernerian school, would be denominated *transitive;* but this, on examination, will probably not be found to be the case. The abundance of extraneous fossils which they contain, their connection with the coal series, and the absence of those external characters, which are usually said to attend this ambiguous and imperfectly defined class of rocks, all conspire to show, that by whomsoever this arrangement may be acknowledged, no part of Derbyshire can be properly considered as belonging to it. In speaking *generally* of the rock formations of the county, their dip may be said to be south-east. The highest strata of Derbyshire will from hence be expected on its southern boundary.

The uppermost regularly stratified mass in Derbyshire, and that consequently which occupies its southern boundary, is a reddish marl. This covers a large extent of surface, and possesses an additional claim to attention, from the gypsum, which, in particular places, is abundantly imbedded in it. At Chellaston, near Derby, this mineral has been got in great quantities from a very distant date; and in two other situations in the same neighbourhood, it has also been worked, but to a less considerable extent. In all these places, it occurs in a tract of land considerably, and abruptly, elevated above the surrounding country. This bed contains fossils or petrifactions, such as *gryphites*, *anomiæ*, *belemnites*, *mytili*, and *pentacrinites*. With these are mixed fragments, and detached masses of rock, brought from a distant part of the country, such as limestone, chalk, coal, fuller's earth, and a variety of others. In one instance, a block of limestone, evidently belonging to the uppermost of the four limestone strata of Derbyshire, the nearest occurrence of which is fifteen or sixteen miles from this point, was seen lying here, which was equal to at least five-and-twenty hundred weight (112 lbs. $\times$ 25.) Nearly the whole of the gypsum furnished from these situations is of the sort denominated by mineralogists *compact* gypsum. Specimens of the *foliated* and *fibrous* varieties occasionally occur, forming a thin bed of four or five inches thick, which lies a short distance above the former; but these, from a strange and unaccountable prejudice, are rejected by plasterers and others who use this mineral, under the impression that they are destitute of the properties possessed by the compact gypsum. The common name for this substance is plaster and alabaster, and its price is from 7s. to 9s. per ton, (120lbs. $\times$ 20) according to quality.

The next stratum which presents itself in Derbyshire, under the red marl, is the yellow, or magnesian limestone. This, however, instead of appearing in the southern districts, as might have been expected, does not occur till we reach Hardwich and Pleasley; but attends the eastern boundary of the county for about fifteen miles previously, just within the edge of Nottinghamshire.

Immediately under the yellow lime, lie the extensive and important range of rocks constituting the coal series of Derbyshire, Yorkshire, and, it may be perhaps added, of Lancashire. These principally consist of alternations of sandstone, clay, bituminous shale, slate-clay, and coal, in different states of induration. The number of sandstone rocks in Derbyshire is about twenty, and of coal beds about thirty, the latter of which vary in thickness from six inches to eleven feet. The total thickness of the coal measures in this county is, as nearly as can be estimated, about twenty-five yards. Their general dip is towards the south-east; but the dislocations and other accidents to which the coal field has been exposed, have produced many exceptions. Notwithstanding this, however, the order of succession in the different rocks may be so confidently relied upon, that the difficulty, in a practical point of view, becomes very much reduced; for wherever any particular stratum can be identified, those which accompany it may be immediately inferred. The value of this knowledge, both in the present, and in the neighbouring counties, has, in many instances, been most abundantly proved to its possessors, by the advantages they have been able to make of it in speculations respecting coal property. This was very strikingly shewn in Staffordshire, (the formations of which are widely different from those now under examination,) where an entirely new series of coals have, within these few years, been discovered, and brought into work, solely by the light which this species of information has supplied. The benefits have not been confined to the individual alone who first disclosed those hidden treasures, but has extended to the whole population of the neighbourhood, and to the kingdom generally.

The whole of the ironstone by which the iron works of Derbyshire are supplied, is furnished from the beds of slate and clay called *bind*, which alternate with the coal. It lies imbedded in these in the form of nodules, and for the most part, consists of the *reniform ironstone*, and *common clay iron-stone*, described by Professor Jameson. The latter occurs under various extraneous forms, such as of muscles, reeds, and ferns. The number of blast furnaces in Derbyshire now (1814), all of which, it is believed, are worked with coke, is about twenty. Several of these are out of blast from the depressed state of the iron trade, and will, in all probability, continue so, until our intercourse with America is revived, not from its direct, but from its indirect influence. The processes employed in the manufacture of iron in this district, do not appear to differ, in any essential point, from those practised with the same materials in other situations. The mechanical aid is in most, if not in every instance, furnished by steam, and the pressure with which the air is thrown into the furnace, on the average, perhaps may be considered as equal to about two pounds and a half on the square inch. To those interested in the manufacture of iron, it may be useful to add, that most of the furnaces in this county are worked with a bright tugen, arising from their being principally employed in producing soft metal. In returning from this digression, it remains only, before quitting the present subjects of inquiry, to say a few words concerning some other general appearances of the Derbyshire coal-field, it being impossible, within the space allotted for these remarks, to convey such a particular account of it as would be requisite for a complete geological acquaintance with its subordinate members. The total depth of the strata composing it, from the under surface of the magnesian limestone to the lowest sandstone, inclusive, is from seven hundred and fifty to eight hundred yards. The last rock alone, which is a coarse quartzose compound, measures a hundred and twenty yards, and is the one called, by Mr Whitehurst, (*Inquiry concerning the Earth*), and by Mr Farey, the *mill-stone grit*. It is much in use in the county for the making of mill-stones, (whence its name,) and also for the hearths of blast furnaces. Wherever it occurs, therefore, the coal may be considered as having all disappeared, and an intimate acquaintance, both with this, and with the yellow lime-stone, becomes, in consequence, a valuable sort of knowledge, since these two strata include the whole of the treasures of ironstone and coal furnished by the district. The first appearance of the limestone here mentioned, within the limits of the present inquiry, is between Wallaton and Bilborough in Nottinghamshire. Proceeding northward, its basset-edge afterwards occurs to the west of Stretley and of Nuttal, at Greasley, to the west of

Derbyshire.

Mineralogy.

Annesley, at Kirkby, Hucknal, and to the west of Teversal; shortly after which it leaves Nottinghamshire, and appears in Derbyshire at Hardwich. From thence it passes by Alt Hucknal, Bolsover, to the west of Clown and Barlborough, and forward into Yorkshire. The line which it describes is very irregular, and there are some circumstances attending its geological history not yet satisfactorily explained. Our knowledge of the mill-stone grit is much more complete, the basset-edge of this stratum being the most distinctly and accurately defined of any in the county. Its first occurrence, to the southward, is at Little Eaton, about three miles to the north of Derby. It may from thence be traced to the west of Holbrook, at Belper, west of Heage; east of Crich, at Tansley; east of Darley in the Dale; east of Becley, on the ridge at the back of Chatsworth house; east of Curbar, at Fox house, and to the east of Hathersage; shortly beyond which point it crosses into Yorkshire. On the eastern side of all these places, therefore, bounded by the yellow lime as before particularized, lies the whole of the Derbyshire coal field; and to the west, the range of limestone and amygdaloid rocks, which remain yet to be described. The facility with which the geology of the county may be studied, by having these points fixed on the memory, must be immediately obvious; and the present sketch, in particular, will derive a very material assistance from it, in the sort of connecting link which it will supply to the scattered remarks here offered in explanation of the principal mineral features of this interesting neighbourhood.

In leaving the mill-stone grit, we next come to a considerable, but irregular formation, called, by Mr Farey, the lime-stone shale. Its thickness varies in different parts of the county from a hundred and forty to a hundred and seventy yards; and it is occasionally accompanied with beds of sandstone, sandstone slate, and black or dark blue limestone. Ironstone is also found in it, in some places, in considerable quantity; but the distance at which this is situated from coal, prevents it from being converted to any profitable use. It is in one of the beds attendant on this formation, that the tripoli, or *rotten-stone* of Derbyshire, is contained. This mineral occurs only with the black limestone, forming a coat on its upper surface of different thicknesses, and appears to be the result of a decomposition which the latter substance has undergone. However improbable such a change may be considered, specimens are in the possession of the writer of these remarks, obtained from the vicinity of Bakewell, in which the transition from one to the other is so distinctly shewn, that it seems impossible otherwise to account for the phenomena. Analysis, it is true, presents at first sight some formidable objections; but they constitute by much the lesser difficulty. Indeed, the change may be supposed to be wholly effected by the solution of the carbonate of lime in the water which filters through the rock, and which thus leaves the silex occupying its original situation.

Under the shale just described, lies the first great limestone rock of Derbyshire. This, in the neighbourhood of Crich, is quarried to an immense extent, for the various uses of agriculture and the arts. The lime yielded by it is of a most beautiful whiteness, and furnishes the bleachers of most of the neighbouring counties with the base of their bleaching liquor, for which it is peculiarly applicable, in consequence of the total absence of all metallic matter, and especially of iron. Beneath this, is a stratum of amygdaloid, or *toadstone*, as it is here termed, of which there are three distinct beds in the county alternating with limestone. They all cross the celebrated vale of Matlock, and either emerge, or basset, in the vale itself, or on the declivity of the ridge which bounds its western side. This was first described by the ingenious Mr Whitehurst, who has given a section, in the second plate to his work, shewing the position of the whole range, in the neighbourhood of Matlock, from the mill-stone grit downwards. The lowest stratum he has there marked, and indeed the lowest which is yet known in Derbyshire, is a fourth bed of limestone, lying under the third toadstone. The total thickness of these is about six hundred and fifty yards; the particulars of which are as follows:

Mill-stone grit	120 yards.
Great shale	150 . . .
First limestone	50 . . .
. . . Toadstone	20 . . .
Second limestone	50 . . .
. . . . Toadstone	30 . . .
Third limestone	70 . . .
. . . . Toadstone	30 . . .
Fourth limestone	130 . . .
	650

There is one error in Mr Whitehurst's delineation of the strata at this point, arising from his having supposed a dislocation or fault to exist in that part of the vale which formed the bed of the river Derwent. This Mr Farey has succeeded in proving to be a mistake, the angle which the different rocks make with the horizon being the same on each side of the valley.

The whole of the lead smelted in the county, is furnished by veins, which traverse the beds of limestone here mentioned. There is not an instance, it is believed, where the amygdaloid has ever yielded a single vein. Hard specimens have been found, in late years, containing small quantities of galena disseminated through them; but these are of very rare occurrence, and appear to be of a newer formation than the strata now under inquiry. One of the most curious and instructive phenomena connected with the history of the present series of rocks, is the occurrence of the veins, which are found at right angles to the dip of the limestone. These exist in each of the four beds, in the same relative situation; so that if the toadstone were removed, they would form one continued vein. The amygdaloid, however, has no corresponding appearance. Immediately at its surface the vein terminates; and miners are now aware that they must pierce the whole substance of the rock, and reach the subjacent limestone, before the object of their search will re-appear.

The lead ore yielded most abundantly in Derbyshire, is the galena, or lead glance. White and green lead ore are also got in considerable quantity, and are now worked in the smelting furnaces. This, however, has only been done within these few years. For many centuries they were thrown aside with the sulphate of barytes, (a *cawk*, as the miners term it,) under the belief that they were alike destitute of metallic matter; and many thousand tons are accumulated near the old workings, which, since the composition of these minerals was discovered, have all been re-explored, and continue, in many places, still to yield a profitable employment. A new species of lead ore was, some years ago, described by Mr Chenevix, as having been found

Derbyshire.

Mineralogy.

at Matlock, consisting of muriate and carbonate of lead. No specimens have since been heard of, although inquiries and searches have repeatedly been made; nor is it known exactly from what part those Mr Chenevix examined were obtained. The most singular production of the lead genus presented in this county, is the *slickenside,* a specular lead glance of Professor Jameson. The phenomena exhibited on piercing the veins of this mineral have been fully described by Mr Whitehurst, and deserve to be noticed in the present account, since, however extraordinary and inexplicable they may seem, they may be confidently relied upon as authentic. The situation of the veins is perpendicular, and the greater part of the materials composing them is common calcareous spar. In the centre, parallel to the sides of the fissure, is a division, the two faces of which are polished, and coated with a very thin film of lead; and these constitute the substance under inquiry. The surfaces are not always plain, but often fluted like the ornamental wood-work of a joiner; and the quantity of lead distributed over them appears to be no greater than would have been left by small pieces of galena being exposed between them to violent friction. The most extraordinary circumstance connected with the slickenside is this, that if a sharp pointed instrument be drawn down the vein with a certain degree of force, the materials emit a crackling noise, and, in the course of a few minutes, explode with considerable violence, the fragments being thrown to a great distance. Several serious accidents at first happened in consequence, and the mines where the phenomenon occurred were for a considerable time deserted, till the workmen, becoming more intimately acquainted with it, found the means of guarding against future mischief, by scratching the substance with their picks, and afterwards retiring to a distant part of the work whilst it exploded.

It is to be regretted, that no particular information can be supplied concerning another product of Derbyshire, which, from its rarity, may be perhaps considered as the next in interest. The elastic bitumen is found in no part of the world but the neighbourhood of Castleton; and here the situation which affords it, is the property of two or three miners, who keep the place shut from every eye but their own, and do not resort to it except in the interval of several years, when they bring out considerable quantities, which are sold at a very high price. Their motive in dealing out the mineral so sparingly, is evidently to enhance its value, contriving just to keep pace with the public demand. It is supposed to be found in very large masses, from the appearance of the pieces these miners produce, which seem as if they had been dug with a spade. *Indurated* bitumen is mixed with the *elastic;* but this is not so rare a product.

Amongst the most abundant minerals of Derbyshire, not hitherto particularized, are carbonate of lime, which exists under almost every crystallized form presented by that substance; fluate of lime, or fluor spar, of which the beautiful ornaments, so well known over the kingdom, are made; sulphate of barytes, both amorphous and crystallised; sulphuret and carbonate of zinc, (blende and calamine,) and copper pyrites. The singular variety of carbonate of lime, called stalactite, is found here very abundantly. A cavern has lately been discovered at Bradwell, near Castleton, the roof of which is almost wholly covered with it. The appearance of this place is particularly beautiful, and is well worth the attention of travellers.

At Ashover, specimens of fluor have been found covered over with crystals of quartz, which is a fact highly deserving of being recorded, as marking the relative age of these substances. Lead glance has also, in the coal districts, been seen crystallised in nodules of iron stone, another circumstance not unworthy of being mentioned, from the information it supplies concerning the different eras at which that mineral has been deposited.

Subterraneous caverns.

Under the subterraneous geography of this interesting county, we may include the remarkable caverns and fissures, which abound in the northern parts of it. There are several small caverns in the neighbourhood of Matlock; but the only ones deserving particular notice, are those of Buxton, Castleton, and Elden Hole.

Poole's Hole.

That in the vicinity of Buxton is called *Poole's Hole,* and is a vast cavern, formed by nature, in the limestone rock. The tradition of the country says, that it was the residence of an outlaw of the name of Poole. The entrance is low and contracted, and the passage at first so narrow, that it is impossible to go forward without stooping; but after having proceeded in this posture for about five-and-twenty yards, the passage widens into a lofty and spacious cavern, the roof of which is beautifully adorned by the pendent stalactites. The droppings of the water, laden with calcareous matter, falling on the rugged floor, forms many masses of *stalagmite,* which the imaginations of those who shew the cavern have likened to many articles of common life. The visitor is conducted into the cavern along a path which winds along the side, at some height from its bottom; but the way by which he returns lies along the bottom. By thus changing the path, an opportunity is furnished of better ascertaining the height and width of the cavern in every part, and of viewing other accumulations of stalactite, some of which are of prodigious size and extraordinary form. The whole length of this subterraneous passage is about 769 yards; it belongs to the Duke of Devonshire, and is granted by him to nine old women, who act as guides, and receive the money given by the visitors. Above Poole's Hole, on the side of the hill, are the kilns and limestone quarries, which give employment to more than a hundred families. They live, like the Troglodites of old, in caverns of the earth; and though exposed to the variations of the seasons, and the ragings of the storm, they exhibit a longevity unknown to the population of the more civilized parts of the kingdom.

Peak cavern.

Peak Cavern, near Castleton, which is also sometimes called the *Devil's Cave,* is one of those magnificent, sublime, and extraordinary operations of nature, which at all times excite the admiration and wonder of the beholder. This cave has been regarded as one of the principal wonders of Derbyshire, and is celebrated by several poets. It is within 100 yards of the town, in a fissure or separation of the rock. It would be difficult to imagine a scene more august than that which the mouth of this cavern presents. On each side, the huge grey rocks rise almost perpendicularly to the height of nearly 300 feet, and meeting each other at right angles, form a deep and gloomy recess. In front, the mouth of the cave, overhung by a vast canopy of unpillared rock, assuming the appearance of a depressed arch, strikes the mind as solemnly grand. This natural arch is regular in structure, and extends in width 120 feet, in height 42, and receding depth 90. In this entrance or first cavern, a singular combination is produced; human habitations and twine manufacturing machines, blending with the sublime features of the natu-

Derbyshire.

ral scenery. After penetrating about thirty yards into the cave, the roof becomes lower, and a gentle descent conducts, by a detached rock, to the interior entrance of this tremendous hollow. Here the light of day, which gradually softens, wholly disappears; and candles are put into the hands of the inspector, to illuminate his farther progress through the stygian darkness of the cavern. During his progress, the visitor is conducted through narrow passages, spacious, and almost roofless openings and hollows, and over a lake of water in a boat. The imagination of the man versed in classic lore, might fancy himself crossing the Styx in the fabled bark of Charon, so deep is the gloom, and so tremendous are the scenes around him.

The entire length of this wonderful cavern, from its entrance to its termination, is above 2250 feet; and its depth, from the surface of the mountain 621 feet. A stream of clear water runs through its whole length. From different parts of the cavern, communications open with other fissures; but none of them equal it, either in extent or grandeur. In extremely wet weather, the interior cannot be visited, as the water fills up a great portion of it, and rises to a considerable height even near the entrance; at other times, the access is not difficult, and quite safe.

Elden hole.

Elden Hole is situated at no great distance from Castleton, on the side of a gentle hill, to the north-west of the village of Peak Forest. It is a deep chasm in the ground, its mouth opening longitudinally in a direction from north to south. Its shape is nearly that of an irregular ellipsis, about thirty yards in length, and, in the widest part, nine broad. The northern end is fringed with small trees, and moss and underwood grow out of the crevices on each side, to the depth of forty or fifty feet. As the fissure recedes from the surface, it gradually contracts; and at the depth of 20 or 25 yards, inclines to the west, so that the eye can no longer trace its course. Many exaggerated accounts and marvellous reports have been propagated concerning this fissure. It has, at one time, been represented as perfectly unfathomable; at others, as teeming at a certain depth with impure air, so that no animal could respire it without immediate destruction. But these descriptions are erroneous, as many persons have, at different times, descended into it, and found that the first landing below the surface was not above seventy yards. The interior of the chasm at the bottom consists of two parts, one like an oven, the other like the dome of a glass-house, communicating with each other by a small arched passage. On the south side of the second cavern was a smaller opening about four yards long, and two high, lined throughout with a sparkling stalactite of a fine deep yellow colour. Facing the entrance, was a column above 90 feet high, of the same stalactite incrustation. On proceeding to the north, there is a large stone covered with the same substance, from which there is a rocky ascent of sixty feet; there is a descent on the other side into another cavern. The side of this, as well as another small cavern, were lined with incrustations of three kinds; the first was a deep yellow stalactite; the second was a thin coating, resembling a light stone-coloured varnish, and reflected the light of a candle with great splendour; and the third a rough efflorescence, the shoot of which was like a rose flower. These facts were communicated to the Royal Society, by Mr Lloyd, the only scientific person who ever descended into it, and are contained in the 61st volume of their Transactions.

Derbyshire.

Picturesque scenery.

Derbyshire has been long celebrated for the beauty of its scenery; and its dales constitute no small portion of its pleasing appearance. The first in the rank of beauty, as well as in size, is the far-famed and romantic *Dove Dale*, a name it has received from the river Dove pouring its waters through it. On entering this enchanting spot, it is impossible not to be struck with the almost instantaneous change of scenery, so different from the surrounding country. Here, instead of the brown heath, or the rich cultivated meadow, rocks abrupt and vast, their grey sides harmonised by mosses, lichens, and yew trees, their tops sprinkled with mountain-ash, rise on each side. The mountains that enclose this narrow dell, rise very precipitous, and bear on their sides fragments of rock, that, at a distance, look like the remains of some ruined castle. After proceeding a little way, a deep and narrow valley presents itself, into whose recesses the eye is prevented from penetrating, by the winding course it pursues, and the shutting in of its precipices, which fold into each other, and preclude all distant view. On proceeding, the scenery of Dove Dale gradually increases in majesty and rudeness. Now those objects, which at a distance seemed to have been ruins, are found to be rude pyramids of rock, and grand isolated masses, ornamented with ivy, rising in the middle of the vale. The rocks which enclose the dale, forcing their scattered and uncovered heads into the clouds, overhang the narrow path that winds through the dark recesses of the dale; and frowning with craggy grandeur, and shaggy with the dark foliage that grow out of the chinks and cling to the asperities of the rock, form a scene in romantic beauty unrivalled. On proceeding about a mile in the vale, fantastic forms and uncouth combinations, detached in vast mural masses, are met. Its sides are perforated by many natural small caverns, which are difficult of access. The length of Dove Dale is nearly three miles; but the views are more limited, from the sinuosity of its course, and its projecting precipices. Through the whole of this majestic feature of country, the river Dove rolls its transparent stream. On the right, or Derbyshire side of the Dale, the rocks are more bare of vegetation, than on the left, or Staffordshire side, where they are thickly covered with a fine hanging wood of various trees and odoriferous shrubs and plants. The character of the scenery is greatly diversified, by the varying form of the rocks, and the changing current of the Dove, the motion and appearance of which is perpetually altering. It is interspersed with small islands and little waterfalls. Dove Dale is no where more than a quarter of a mile wide, but in several places it almost closes, and hardly leaves a passage for its narrow river. The rugged, dissimilar, and frequently grotesque and fanciful appearance of the rocks, distinguish the scenery of Dove Dale from every other in the kingdom. On the whole, it is one of the most pleasing pieces of scenery of the kind that can any where be met with. It has something peculiarly characteristic. Its detached, perpendicular rocks, stamp it with an image entirely its own; and, for that reason, it affords the greater pleasure. This dale was a favourite resort of J. J. Rousseau, when he resided in its neighbourhood in the year 1767.

The other dales of Derbyshire, are Monsall, Middleton, Darley, Matlock, Lover's Leap near Buxton, Castleton, and that of the Via Gellia; all possessing great picturesque beauty, but bearing so strong a resemblance to Dove Dale, though on a smaller scale, that we shall not insert a separate account of each.

Derbyshire.

Buxton waters.

A description of its mineral waters deserves a distinguished place in an account of Derbyshire; as no county excels it in the number and variety of medical springs. The tepid waters of Buxton were held in great estimation as far back as the time of the Romans, who made a great use of them; as, about a century ago, the remains of a Roman bath were discovered near the source of one of the springs. From their time to the year 1571, when Dr Jones published a work on their virtues, which gave them great celebrity, they were never entirely forsaken. The first convenient house for the reception of visitants, was erected a short time previous to that publication by the Earl of Shrewsbury. This building occasioned the waters to be much more resorted to than heretofore, by all ranks of people. It was much frequented in the reign of Elizabeth, at which time Mary, Queen of Scots, paid it a visit, and since that period the yearly visitors have been regularly on the increase. The baths are five in number, inclosed in the building called the Crescent. The public baths are very large, but the private are small. The two springs which principally supply these, rise in a stratum of black limestone on the south-east side; but the water also bubbles up through the chinks between the stones with which the bath is paved. It is calculated, that all the springs throw out the water at the rate of sixty gallons in a minute. On a chemical analysis, Buxton waters have been found to be slightly impregnated with mineral matter, particularly calcareous earth, sea salt, selenite, and acidulous gas, with, perhaps, some other permanently elastic vapour. The almost invariable temperature of the water is 82° of Fahrenheit's thermometer; and is clear, sparkling, and grateful to the palate. The temperature of the baths is extremely agreeable to the feelings. The beneficial tendency of the water is particularly apparent in gout and rheumatism; in nephritic and bilious disorders, and debility of the stomach and intestines. The water, when drunk in any considerable quantity, occasions many feverish symptoms, such as a sort of giddiness, attended with a sense of universal fulness and drowsiness, and is found to possess a binding and heating quality; but in a few days these sensations go off, and it often happens that the patient does not feel the full benefit of the waters till he has left the place.

Matlock spring.

The Matlock warm springs are similar, in many circumstances, to those of Buxton. They issue from between fifteen and thirty yards above the level of the river; higher or lower the springs are cold, differing in nothing from common water. The quality of these waters has been examined by several medical gentlemen, who have borne testimony to their beneficial effects. The temperature is rather lower than that of the Buxton baths, being from 68° to 69°, and they exhibit more fixed air. They are agreeable to the palate, and impregnated with selenite, or earthy salts, and a small proportion of sea salt. Matlock contains three cold (or of the natural temperature), and two artificially warm baths.

Several theories have been advanced, in order to account for the natural heat of the Buxton and Matlock water; the most ingenious of which was proposed by Dr Darwin. He supposes that the origin of the heat of these waters is in the steam raised from deep subterranean fires. The strata in this part of Derbyshire, he says, consist of beds of limestone and lava (toadstone), which lie reciprocally on each other; and he sums up the whole argument, by stating the supposition, that "the steam rising from subterraneous fires, is owing partly to waters slowly subsiding upon those fires, and to limestone gradually calcined by them; from whence," he supposes, "it might happen, that this steam, rising through the perpendicular clefts in the super-incumbent rocks, must be replete with carbonic acid gas, and some phlogisticated air. If," continues he, "this steam, so impregnated, be condensed in limestone strata, the fixed air in this hot steam will supersaturate itself again with calcareous earth; which is what precisely happens at Matlock, where the waters are replete with calcareous particles, as appears by the copious deposition of tripha, or calcareous incrustation, along the channels in which they flow.

To this theory has been objected, that it is difficult to admit, that a subterranean fire could exist for so long a series of years as to keep up a regular and undiminished heat, capable of producing the effect above described; and that, whatever validity there may be in such an argument, it will be quite as difficult to imagine, that a bed of pyrites (the decomposition of which was said to have caused the heat) should be more inexhaustible than a body of unkindled fire." A new theory has lately been advanced: From the detection of saline matter in these waters, and the well-known property of sea salt to dissolve lime, it is conjectured, that the waters of these springs being previously impregnated with acid, become saturated with lime in its passage through the strata before described, and is afterwards decomposed by the addition of pyrites dissolved in the rain water, which percolates through the superincumbent strata; for pyrites containing sulphur, the heat that takes place during the solution of the pyrites, will necessarily disengage a certain proportion of acid; and sulphuric acid will immediately unite with lime when held in solution by the weaker acids, and, when united with it, fall down in a calcareous sulphate, and heat is again generated during the process.

Kedleston spring.

Another mineral spring, of a different description, is that of Kedleston, near Derby. It is situated near the seat of Lord Scarsdale, whose father, about fifty years ago, erected a building inclosing the spring in the centre, and surrounded by two warm and two cold baths. The Kedleston water is similar to the Harrowgate, but not so strongly impregnated. The spring is pretty copious; and the water, in a glass, looks very clear and transparent, but in the well it appears of a blackish blue colour, tinged with purple; and any substance thrown into it assumes the same appearance. Its smell is fetid; and though, on its first being put in a glass, it appears clear, yet, when it has stood for some time, a duskishness comes on, which is soon followed by a total loss of scent and taste. It is impregnated with sulphur, calcareous earth, and sea salt. It is principally valued and resorted to on account of its antiscorbutic qualities. By external application, it has been found efficacious in various cutaneous diseases, and more particularly in ulcerous complaints. It is frequented during the summer by a good deal of company. The temperature of the water is 53° of Fahrenheit.

At the distance of about half a mile from the above-mentioned place, is a large and strongly impregnated chalybeate spring, or rather a carbonated chalybeate, with the addition of a saline substance. It is chiefly drank for its tonic qualities: it has been found serviceable in chlorosis, flatulency, indigestion, and debility: it is much frequented. The temperature of the spring is nearly $49\frac{1}{2}$°.

Antiquities.

The antiquities of Derbyshire may be divided into

Derbyshire.

British antiquities.

British, Roman, and Saxon. Under the first head we may place the barrows, which are numerous in the northern part of the county; and a druidical temple, a circle of large stones, called Arboc-lous, situated on a barren eminence near the road from Wirksworth to Buxton. There is another smaller circle on Stanton Moor, together with others in different parts. There are also several large rocking-stones, and other remains of druidical superstitions, to be found in many of the northern districts.

Roman antiquities.

Among the Roman remains discovered in Derbyshire, the roads that cross it in two directions, and which may still be traced through a great part of their course, are the most prominent. The one, called the *Ilkenild-street*, comes out of Staffordshire, and runs in a north-eastern direction, on the western side of the county, as far as Chesterfield, and perhaps from there to York. The other road that has been investigated is called the *Bathway*, or *Bathing-gate*, and extends from Brough to Buxton, a distance of nearly twenty miles. The remains of Roman encampments are discoverable on Pentridge common, and on the top of Mam Tor, near Castleton. The ruins of the latter, still discernible, are considerable. It extended from north-east to south-west, along the ridge of an eminence, and occupied more than fourteen acres of ground. Chesterfield, we have no doubt, from its name, was a Roman station; but there are no remains of that people discoverable in the town, or its immediate vicinity. At Little Chester, near Derby, some walls remain.

Saxon antiquities.

Under the head of Saxon antiquities, we shall, for the sake of brevity, include the remains of ancient edifices, to whatever people they may owe their origin. At Castleton, there are considerable remains of the castle which gave it the name it bears. Its situation is very elevated, and the almost perpendicular chasms that nearly insulate the eminence it occupies, must, prior to the invention of gun-powder, have rendered it impregnable. This castle is of considerable antiquity, and is supposed to have been a fortress, (the town below is walled,) and a place of royal residence, in the Saxon times. Some antiquarians are of opinion that it is of Norman origin, and erected by William Peverel, natural son of the Conqueror. To him it is ascribed by the tradition of the neighbourhood; and its ancient appellation of *Peverel's Place in the Peke*, countenances this opinion. At the compilation of Domesday, the Peverels were its possessors; for about that time a tournament was held there, when Gevarine de Mez, a branch of the house of Lorraine, and an ancestor of the Lords Fitz Warren, vanquished a son of the king of Scotland, and a Baron of Burgoyne, and obtained the prize, which was a daughter of William, a sister's son to Pain Peverel, lord of Whittington, in the county of Salop, for his wife. Since that time, this castle and its demesne have passed through many possessors, and forms a part of the duchy of Lancaster. The present constable of the castle is the Duke of Devonshire.

There is also a considerable remain of *Codnor Castle*. In the early part of the thirteenth century, there are accounts of this castle; and in the reign of Henry III. it was the chief seat of the Barons Grey of Codnor. During the time of Henry VII. it passed from that family; and the estate is now in the possession of a private gentleman. Codnor Castle was situated on elevated ground, commanding an extensive prospect to the east. The wall on the eastern side is yet standing to a considerable height, and the wall on the west side of the court is entire. On the eastern side was a broad deep ditch, or moat; its remains indicate great strength. The park belonging to the castle comprehended more than 2000 acres of land.

At *Horsley*, in the neighbourhood of Derby, formerly stood a castle. It was built early in the thirteenth century, when one of the Ferrers, Earls of Derby, was governor of it. It was given by Henry VIII. to the Duke of Norfolk; but, upon the attainder of his son, it escheated to the crown, and was given to one of the Stanhope family. At present, a very small portion of its ruins is visible. The site of it belongs to the Earl of Chesterfield.

The vestiges of an ancient castle may be traced at *Melbourne*; but by whom, or at what period it was built, it is now impossible to ascertain. That it existed in the time of Edward III. is certain. Camden says, "not far from the Trent stands Melborn, a castle of the king's, now decaying, where John, Duke of Bourbon, taken prisoner in the battle of Agincourt, was kept nineteen years in custody." Leland says, that in his time "it was in tolerable and in metely good repaire."

In former times, *Duffield* was a place of great consequence, as it was the residence of the Ferrers, Earls of Derby. On elevated ground, at the north-west end of the village, stood their castle. At the conclusion of the thirteenth century, or the beginning of the following, this fortress was destroyed. For Robert de Ferrers, the last earl, joining the barons in a rebellion against Henry III. that monarch sent his son, Edward I. in 1264, into the county of Derby, in order to ravage, with fire and sword, the lands of the earl of that name. At that time, it is most likely this castle was destroyed; and so complete was the ruin, that not a vestige can now be traced of its ancient grandeur; not a stone remains to tell the inquisitive antiquarian where once it stood. But the site is known.

Ruins.

The most considerable ruin, in extent, to be found in the county of Derby, is that of the *manour-house of South Wingfield*. Its remains, which are extensive, exhibit many specimens of original magnificence. It was built, according to Camden, by Ralph, Lord Cromwell, in the reign of Henry VI. It consisted of two square courts; the northern of which was built on all sides, and the southern on three. Beneath the hall is an extensive vault, curiously and beautifully arched with carved stone, having a double row of pillars running up the middle, all in perfect preservation. This mansion was castellated and embattled; at each corner stands a tower; but that at the south-west rises higher than the rest. Mary Queen of Scots was confined for many years at South Wingfield. This edifice is supposed to have first suffered from an attack of the Royalists, in the time of Charles I. a party of whom, under the command of the Duke of Newcastle, in November 1643, took it by storm. But shortly after, Sir John Gill of Hopton assaulted it with cannon, and after making a considerable breach, obliged the garrison to surrender. In the year 1646, an order was issued for dismantling it. From that time it has been neglected, and falling into ruin.

At the time of the dissolution of the monasteries and abbeys, in the reign of Henry VIII. there were several richly endowed in Derbyshire. The Abbey of Dale, was a religious house of the Premonstratentian order, and inhabited by eighteen abbots. The whole revenue of this house was considerable, amounting to L. 144, 12s. besides some hundreds of acres of land, and many valuable and highly profitable grants. The arch of the east window of the church, is the only part that now

Derbyshire.

remains of this establishment. At Darley, in the immediate vicinity of Derby, was another abbey. The canons of the monastery of Austin friars of St Helen's, Derby, removed here in the early part of the reign of Henry II. The endowments of this house were great, besides its possession of many churches in different parts of the county, as well as extensive grants. At the dissolution, its annual revenue was valued at L.285, 9s. 6d. Soon after it was sold, and the principal buildings destroyed; but a few walls, some out-buildings, and a house called the chapel, now converted into dwelling-houses, may still be seen, and serve to point out the situation of the abbey. The priory of Breadsall, was the house of Friers Heremites, founded in the reign of Henry III. and was afterwards converted into a small priory for the order of St Austin. Its revenues did not amount to more than L.13, 0s. 8d. The Abbey of Beauchief, or *de Bello Capite*, was situated at a village of the same name, in a beautiful little vale, within a short distance of Sheffield. It was founded between the years 1172 and 1176, by Robert Fitz Ralph, Lord of Alfreton. It was dedicated to Thomas à Becket. Besides the endowments of its founder, many other grants and privileges were bestowed upon it. On the dissolution, its revenues were estimated at L.157, 10s. 2d. Of this extensive building, only a small part of the chapel now remains.

Prior to the year 660, there was a monastery of religious men and women at Repton, a village a few miles to the south-west of Derby; but the Danes, on their arrival in England, destroyed it. In 1172, it was rebuilt by Matilda, wife of Ralph, Earl of Chester, who founded a priory of canons of the order of St Austin. This religious house continued till the dissolution, when its revenue was found to be, according to Speed, L.167, 18s. 2d. Beneath the chancel of the church at this place, an ancient crypt was discovered some years ago. It is supported by two rows of round Saxon wreathed pillars, and supposed to be formed in Alfred's reign. A free school, with considerable endowments, was erected at Repton in the reign of Henry VIII. by the will of Sir John Port of Etwall, and continues to the present time in a very flourishing state.

Of the market towns of Derbyshire, the following are the principal: Chesterfield, Ashbourn, Belper, Alfreton, Wirksworth, Bakewell, Tideswell, Chapel-in-le Frith, and Wrinster; to which we may add Buxton and Matlock, of more recent origin: an account of the principal of which will be found under their proper names.

Principal county seats.

Derbyshire possesses several magnificent gentlemens' seats; but the following deserve particular notice: About two miles from Bakewell is *Haddon Hall*, a venerable mansion belonging to the Duke of Rutland. It is situated on a bold eminence on the banks of the river Wye, and consists of several apartments and offices, erected at different periods, round two quadrangular courts. The most ancient part was built in the reign of Edward III.; the other parts were erected from that time to the reign of Elizabeth, when the last addition was made. It was stripped of its ancient furniture about fifty years ago, and is now in a state of dilapidation. The extensive park is divided into portions; and its gardens, which consist of terraces ranged one above the other, entirely neglected. Haddon Hall is considered as one of the most complete baronial residences now remaining; and though not at present inhabited, nor in very good repair, is extremely interesting, from the many indications it exhibits of the festive manners and hospitality of our ancestors; and of the inconvenient, yet social arrangement, by which their mode of life was regulated.

Hardwicke-Hall, a celebrated seat belonging to the Duke of Devonshire, is situated on an elevated ridge of ground near the north-eastern boundary of the county. It stands in a fine and extensive park, well wooded; and between the trees, the towers of the edifice emerge with great majesty, their summits appearing covered with the lightly shivering fragments of battlements: these, however, are soon discovered to be carved open work, in which the letters E. S. frequently occur under a coronet; the initials, and memorials of the vanity, of Elizabeth, Countess of Shrewsbury, by whom this edifice was built. The house is of stone, having a lofty tower at each corner: in the front is a spacious quadrangular court, surrounded by a high stone wall. It affords a good specimen of English architecture in the 16th century. Mary Queen of Scots was confined here for many years, when under the care of the Earl of Shrewsbury; and a bed of tapestry work, on which she employed herself, yet remains in good preservation. But Hardwicke Hall is principally celebrated for its gallery of pictures: it is 195 feet long, and contains portraits of many illustrious characters by the first masters.

Chatsworth, another magnificent seat belonging to the Duke of Devonshire, was once reckoned one of the seven wonders of the Peak. It stands on a gentle acclivity, near the bottom of a high hill, finely covered with wood, in a narrow and deep valley, bounded by bleak and elevated tracts of land. The house, which is built in the Ionic order, with a flat roof, surrounded by a neat balustrade, may be considered as a noble specimen, of that highly decorated style of building, imported from Italy about 130 years ago: magnificent and heavy; expensive, but devoid of taste. Its form is nearly a square of about 190 feet. The interior as well as exterior of this edifice, is characterised by heaviness and gloom; and though splendidly ornamented with magnificent painted walls and ceilings, presents but few of those captivating productions of the pencil, which embellish the apartments of many other mansions in this county. It possesses, however, some attractions of another kind, which amply repay the visitant's attention: these are the beautiful carved ornaments by Gibbon. The water-works in the garden, are the principal objects of curiosity at Chatsworth. The famous cascade, one of those grand water-works, which half a century ago rendered it the greatest wonder of the neighbouring counties, has not yet lost its celebrity. It consists of a series or flight of steps, extending nearly 200 yards from one end to another, down a steep hill. This cascade is put in motion by turning a screw, at the temple near its summit, and the water rushes in vast quantities, and with great force and noise, from the dome of the temple, and from a great variety of dolphins, dragons, and a number of other figures that ornament it. There are also several canals, basins, and fountains; one *jet d'eau*, throws the water ninety feet high. All those works are supplied from a large reservoir of water on the top of the hill, covering fourteen acres of land, from whence the water is conveyed in pipes laid in the ground. Chatsworth has a very extensive park; and is often the residence of the present duke.

But *Kedleston-House*, the splendid mansion of Lord Scarsdale, is by far the most magnificent seat in the county. It is situated about three miles to the north-west of Derby, on a gentle ascent on an open piece of ground in the park. The front of this noble edifice measures 360 feet in length, and is a grand specimen

Derg || Descartes.

of Adams' architectural skill. The front is of white stone, and divided into three parts: a centre and two pavilions, connected to it by corridors of the Doric order, taking a sweeping form: that on the right, comprising the kitchen and offices; that on the left, consisting of Lord Scarsdale's private apartments. In the centre of the north front is a double flight of steps, leading to the grand portico, whose pediment is supported by six Corinthian pillars, proportioned from those of the Pantheon at Rome. The hall is planned after the Greek hall of the ancients. The coved ceiling is supported by twenty Corinthian columns of variegated marble, twenty-five feet high. The other apartments are the music-room, the drawing-room, the library, and the grand saloon, a most elegant room. In all these, there are innumerable paintings by the most eminent old masters, forming a private collection seldom surpassed in this country. Indeed, elegance and taste, characterise every thing within and about Kedleston. The park is very extensive, well stocked with deer, and adorned by a great number of venerable oaks. In front of the house, is a fine sheet of water, broken into several falls; and young plantations surround the whole visible horizon. Beside the seats above mentioned, there are Wingerworth Hall, the seat of Sir W. Hunloke; Willersley Castle, the seat of R. Arkwright, Esq. and many others of lesser note.

Manufactures.

The produce of the manufactories of Derbyshire, are various and extensive. The manufactories of cotton into thread, stockings, and calico, at Cromford, Belper, Derby, and other parts; of wool into hose, and cloth, on the borders of Nottinghamshire, and in the neighbourhood of Tideswell; of iron on the north-east side, and adjacent to Yorkshire; of silk, and also of ornaments made of spar, at Derby, are the principal, and employ some thousands of its population.

Such is a sketch of the history of the county of Derby, one of the most interesting in England. No one exhibits such a variety of scenery, or produces so rich a store of mines and minerals. It possesses some highly cultivated tracts, and a spirit of improvement has taken hold of its numerous and highly respectable country gentlemen. It numbers among its sons, many that have been, and are still eminent for science and knowledge; and its peasantry are highly moral, and in a considerable degree enlightened. (D.P.D.)

DESCARTES, RENE DU PERRON, a celebrated metaphysician, mathematician, and natural philosopher, was descended of an ancient family, and was born at La Haye in Touraine, on the 31st of March 1596. He was the youngest of three children, and his mother died a few days after his birth of an illness which had been contracted during pregnancy. Although his father married a second wife, by whom he had two children, yet the cares of his new family did not interfere with the education of young Descartes, whom he was in the habit of calling "his philosopher," from the insatiable desire which he displayed to discover the causes of every thing around him. From the instability of his health, he was under the charge of females till near the winter of 1604, when he was sent to the Jesuits college of La Fleche, and put under the special charge of M. Charlet, a relation of his own, and rector of the college. After having spent five years in the study of the learned languages, in which he made uncommon proficiency, his attention was directed to logic and moral philosophy, from which he derived little satisfaction; but he was amply repaid for this unprofitable labour, from the delight with which he was inspired by his mathematical studies, into which he was initiated during his last year at La Fleche. Having received a dispensation from the strict scholastic discipline of the college, in consequence of the infirm state of his health, Descartes was enjoined by the rector to recruit himself by lying long in bed. He thus formed a habit, which continued during the rest of his life, of devoting these hours of quiet to those subjects of deep meditation, for which the greatest abstraction was necessary. When he had finished his course of study at La Fleche, which had lasted eight years and a half, he returned in the month of August 1612 to his father's house, accompanied with the blessings of his preceptors; but though he felt the warmest gratitude for the kindness and the instruction which he had received, yet he was dissatisfied with himself, and seemed to think that the utmost amount of his acquirements, was a full conviction of his own ignorance, and of the uncertainty of all human knowledge. He, therefore, resolved to abandon his studies; and, in consequence of this resolution, he went to Rheims to revisit his family, and he spent the whole of the year 1613 in riding, and fencing, and other exercises, which were considered as preparatory to a military life. Dreading, however, that his constitution was not sufficiently robust for the profession of arms, his father sent him to Paris in the spring of 1613, without any other guide than his valet de chambre, and left him the uncontrouled management of his time. A love of pleasure, and a strong propensity for gaming, in which he greatly excelled, were the natural consequences of his father's indiscretion; and had he not been introduced to Claude Mydorge, who succeeded Vieta in the reputation of being the first mathematician in France, and renewed his acquaintance with his fellow student Mersenne, he would probably have abandoned himself wholly to every species of intemperance. By their remonstrances, however, he was reclaimed from his vicious pursuits, and he gradually acquired that love of study, which had formed such a striking feature in his early character. His separation from Mersenne, who was sent about the end of the year 1613 to Nevers, to teach philosophy to the young religious of his order, produced a complete change in Descartes' views. He retired to the Fauxbourg of St Germains, with one or two domestics, and devoted himself wholly to the study of mathematics. His old companions sought for him in vain; and he had even the precaution to take his exercise in places where they were not likely to discover him. In this state of seclusion, Descartes spent two years. His precautions having been relaxed, his companions soon discovered the place of his retreat, and again allured him to the pleasures and amusements which he had forsaken. They had lost, however, their former relish, and he determined to try a military life. In May 1617, he set off for Holland, and entered as a volunteer in the Dutch army, under Prince Maurice. While he was quartered at Breda, some person had affixed on the corners of the streets a mathematical problem, and required the solution of it. Descartes observing a number of the passengers reading this placard, which was in Flemish, requested one of them to translate it into Latin. The person to whom this request was addressed instantly complied with it, but on the condition that he would transmit him the solution of the problem. Descartes accepted of the offer in a way so determined, as to excite the astonishment of the other party, who could scarcely believe that a young officer could solve a problem which appeared to him so difficult. Descartes found, from the card which he received, that he had been conversing with Isaac Beeckman, the Principal of the college of Dordrecht; and he was therefore doubly solicitous about the solution of the problem. On the following day he went to the house of Beeckman with the problem resolved, and offered also to show him the construction of it. Beeckman was surprised at this effort of his young friend, but was still more astonished when he found, by his conversation, that he was deeply versed in the knowledge of the times, and had gone far beyond himself in those sciences which had been the particular object of his own studies. After this singular rencontre, Beeckman and Descartes were friends and correspondents during the remainder of their lives.

When Count Maurice had become prince of Orange, in 1618, and carried his army against the Armenians, Descartes remained at Breda, where he composed his *Compendium Musicæ*, which was afterwards published at Utrecht in 1650, in 4to; at Amsterdam in 1656; and at London, in English, in 1653. Descartes spent a great part of his time in the society of Beeckman, who came to Breda in order to be near his learned friend; and it was at this time that he laid the foundation of several works, which he afterwards published.

The state of inactivity of the Dutch army, induced Descartes to quit Holland, and repair to Germany, where the coronation of a new emperor, the revolt of the Bohemian states, and the war between the Catholics and Protestants, had created a great ferment. He, accordingly, set out from Breda in July 1619, and, passing through Maestricht and Aix la Chapelle, he assisted at the coronation of Ferdinand II. at Frankfort. He now entered as a volunteer into the army of the Duke of Bavaria; and went into winter quarters at Neuburg on the Danube, in October 1619, where he devoted himself, without interruption, to his favourite studies. On the 18th of November 1619, as he himself informs us, when he was lying in bed, filled with enthusiasm, and occupied with the thought of having discovered the foundation of true science, he had three consecutive dreams, in which he thought that God had pointed out to him the line of life which he should follow, and the real method of investigating truth. Descartes believing that these dreams were of heavenly inspiration, prayed to God to assist him in his investigations; and in order to interest the Holy Virgin in the same cause, he vowed to perform a pilgrimage to our Lady of Loretto, which he accomplished after a lapse of some years.

Under the influence of similar feelings, he applied for aid to the Rosicrucians, who boasted of being divinely inspired; but he could find none of the sect who were able to unfold their system, and he was compelled to seek for truth in the only way in which it can be found, in the humble path of sober and patient inquiry. The Bavarian army having advanced to Suabia, Descartes went to Ulm in June 1620, and spent the greater part of the summer in that city. Here he became acquainted with John Faulhaber, a very learned man; and it is said that he at this time discovered the art of constructing, in a general manner, all sorts of solid problems, reduced to an equation of three or four dimensions. Descartes accompanied his regiment to Bohemia, and was present at the famous battle of Prague.

About the end of the year 1621, he quitted the Bavarian service, and entered the army of the Count de Bucquoy, which marched into Hungary in April. Descartes was present at the siege of Presbourg, Tirnaw, and several other places, where he is said to have signalized himself; but the raising of the siege of Neuhausel, where Bucquoy was killed, gave him a disgust with a military life. Having left the army, he visited Moravia, Silesia, Poland, Pomerania, and the shores of the Baltic; and, in order to see West Friesland with advantage, he purchased a boat, and embarked with a single valet. The sailors, thinking that he was a foreign merchant, and that much money would be found among his baggage, resolved to throw him into the sea, and seize his property. Imagining that he was ignorant of their language, and dreading no opposition from the tranquillity of his temper, they had the audacity one day to talk of the plan in his own presence. Descartes saw the danger to which he was exposed; and rising on a sudden, he drew his sword with the greatest fury in his countenance, spoke to them in their own language, and threatened to stab the first person that dared to insult him. Overawed at this unexpected display of courage, the sailors abandoned their cruel design, and carried Descartes in safety to the place of his destination. From West Friesland he went to Holland and the Netherlands, and he returned in safety to his father's house at Rennes, in the month of March 1622. His father took this opportunity of making over to him the inheritance which he derived from his mother, and which was situated in Poitou. After having resided for some time in Paris, and freed himself from the imputation of being a Rosicrucian, which had been fixed upon him by some of his enemies, he devoted himself to the study of mathematics and moral philosophy. In May 1623 he returned to Rennes, from which he repaired to his estate in Poitou, the greater part of which he sold with his father's consent. Descartes now resolved to perform a journey to Italy. After passing through Switzerland, the Grisons, and the Tyrol, he arrived at Venice, and afterwards performed the pilgrimage which he had promised to Loretto. In November 1624, he arrived in Rome, where he employed his time in studying the manners and dispositions of the people. In 1625, he left that city, and returned to Paris by the way of Tuscany and Savoy. The reputation of Descartes had, by this time, been widely extended; and his company was courted by all the learned men of Paris. In the years 1627 and 1628, his friend Mydorge directed his attention to the method of grinding lenses and mirrors; and Descartes arrived at a great degree of perfection, in executing even those of a hyperbolic and an elliptical form, which he found of great service in investigating the phenomena of vision, reflexion, and refraction. After having again resorted to a retired mode of life, and been again discovered by his friends, he went to see the siege of Rochelle, from which he returned to Paris; but the interruptions which he again met with, inspired him with a firmer resolution than he had yet taken, of retiring completely from society. He accordingly left Paris in 1628, committing the charge of his affairs to the Abbe Picot; and after having spent four of the winter months in the country, he went to Holland in March 1629. From Amsterdam he went to Egmond, a delightful village near Franeker in Friesland, where he fixed his residence.

In this sequestered spot, he turned his attention to metaphysics, theology, meteorology, and dioptrics; but as he had left in France almost all his tools for grinding lenses, he could not proceed so smoothly with his optical studies. An account of the parhelia which were seen at Rome on the 20th of March 1629, had been sent to him, both by Mersenne and by Renier or Reneri; and he was thus led to compose his valuable treatise on meteors, which also contains his discoveries respecting the rainbow.

After he returned to Amsterdam, he spent the whole of the winter of 1629 in chemical experiments, and in the dissection of animal bodies; and he informs us, that he every day found something new in these sciences. Having received a visit from his friend Mersenne, Descartes went to England in 1631; and in the neighbourhood of London, he made a number of observations on the variation of the needle. Henry Reneri, who was the first person that embraced the opinions of Descartes, was elected Professor of Philosophy at Deventer, a circumstance which induced the latter to take up his residence in that town in the spring of 1633. Here he completed several works which he had formerly begun, but particularly his Dioptrics, and his "Treatise on the World;" and he applied himself principally to the study of astronomy. His "Treatise on the World" having been carefully revised, he was on the eve of sending it to Mersenne to have it printed at Paris with the royal privilege; but having heard of the persecution of Galileo, he was obliged to abandon this design, as his own work contained similar opinions.

From Deventer, Descartes went to Amsterdam in 1634, and he soon after performed a tour through Denmark and the lower parts of Germany with his friend M. De Ville-Brissieux, a celebrated mechanic and chemist of those times. From Amsterdam, to which he returned, he again went to Deventer, whence he set off to Leuwarden in Friesland, where he composed his treatise on mechanics. In March 1636 he returned to Amsterdam; and, in passing over the Zuyder Sea, he made some curious observations on the coloured rings with which candles are sometimes surrounded.

On the 4th May 1637, he obtained, in the most honourable manner, the royal privilege, not only to publish those treatises which he had prepared, but also every thing that he had written, or might still write, during the rest of his life. These treatises were published anonymously at Leyden, in 4to, and entitled, *Discours de la Methode pour bien conduire sa raison, et chercher la verité dans les sciences. Plus, la Dioptrique, les Meteores, et la Geometrie qui sont des Essais de cette methode.* In presenting copies of this work to his friends at Paris and Rome, Descartes omitted to send one to Roberval, professor of mathematics at Paris; and it is said, that this neglect was the cause of that bitter animosity which he ever afterwards felt and displayed towards Descartes.

Among the numerous combatants that were called into the field by the publication of Descartes book, the most distinguished was M. Fermat, counsellor to the parliament of Thoulouse, and one of the finest mathematicians of the age. Fermat stated several objections to the dioptrics of Descartes, and, before he received his reply, he sent him a copy of his book *De maximis et minimis*, under the name of M. Carcavi, a friend of his own. This present gave rise to a new dispute, which was carried on at Paris through the medium of Mersenne and Mydorge on the part of Descartes, and M. Pascal and Roberval on the part of Fermat. The dispute became at last personal, owing to the intemperate hostility of Roberval; but Fermat had the good sense to disapprove of this conduct, and it had the effect of producing a complete reconciliation between the two contending mathematicians. Descartes took a keen part against Roberval, in the question which was now agitated in France respecting the cycloid; and his time was almost wholly occupied in unprofitable replies to the objections which were every where urged against his philosophy.

The Cartesian doctrines were now making rapid progress in Holland, in consequence of the zeal of Reneri, who had been removed from the university of Deventer to that of Utrecht. One of his disciples, named Henry Regius, imbibed the same views with his master, and was so eager to make himself acquainted with the new philosophy, that he went to receive instructions from Descartes himself. The death of Reneri, which happened about this time, removed the restraint which his high reputation had laid upon the enemies of Descartes at Utrecht, and called forth the hostility of Voetius, who was professor of divinity in that university. This theologian, who was also the principal clergyman in the city, published theses in June 1639, in which he branded the new philosophy as atheistical, and as pernicious to the Protestant religion, and the repose of the United Provinces. These insinuations were ably repelled by his colleague Regius. The professor of divinity, irritated at the ability of this reply, determined to ruin the reputation of Regius as well as that of Descartes. In Regius's Lectures on Medicine, he sought for the opportunity which he wished; and he soon found, that this enlightened physician had taught the heretical doctrine of the circulation of the blood, which had been discovered by our countryman Harvey. A complaint was, on this ground, laid before the university, and Voetius had the address to interest even the rector and the personal friends of Regius and Descartes, against the new opinions; and to induce the university to publish an ordonnance, to prevent the dissemination of opinions contrary to its statutes. The troubles which were excited by this dispute, attracted the notice of the civil power; and it was at last agreed, at the suggestion of Descartes, in his answer to the ordonnance, and with the approbation of the magistrates of Utrecht, that Regius should be allowed to teach the new philosophy, but that he should be admonished to moderate his zeal, and to modify some of the boldest of his opinions.

The opinions of Descartes were received in England with great avidity. Lord Charles Cavendish, the brother of the Duke of Newcastle, who was enamoured of the Cartesian philosophy, invited Descartes, and his friend Mydorge, to settle in England. Descartes seemed disposed to accept of the invitation, particularly when he was assured that the king was a Catholic in his heart; but Mydorge, who had a family at Paris, did not comply with the same readiness. Charles I. promised to make a handsome provision for the two mathematicians; but the commencement of the civil war induced all parties to abandon the arrangement.

The tranquillity of Descartes was about this time disturbed by a dispute with the Jesuits, in which he was embroiled by M. de Saumaise. M. Bourdin, professor of mathematics in the Jesuits college of Clermont, attacked the tenets of Descartes, but particularly his dioptrics, in theses, which were supported on the 30th of June 1640, and his friend Mersenne defended him.

as usual; but believing that the whole company of Jesuits were combined against him, and that Bourdin wished to throw ridicule upon his opinions, Descartes lost the usual serenity of his temper, and declared war against the whole society. He addressed a letter, full of vigour and respect, to the rector of the college, complaining of the conduct of Bourdin; but the rector left it to his colleague to defend himself, and the dispute was long carried on between the Jesuits and the Cartesians without any profitable effect. During this dispute, Descartes lost his father, and his daughter Francina, to whose mother there was no proof of his having been married, and a long time elapsed before he recovered from this severe affliction. In 1640, Louis XIII. at the advice of Cardinal Richelieu, invited Descartes to Paris, upon the most honourable terms; but the high inducements which were held out, could not prevail upon him to leave his retirement. In 1641, Descartes published his *Meditations touchant la première philosophie, ou l'on demontre l'existence de Dieu, et l'immortalité de l'ame,* which involved him in fresh contentions. His enemy Voetius, who was now promoted to the rectorate of the university of Utrecht, renewed his attacks against Regius and Descartes, and succeeded, after many intrigues, in procuring a decree of the magistrates, and a resolution of the university, to prevent the former from teaching any thing else but medicine. But while Cartesianism was thus persecuted in Holland, it was making rapid advances in France among the Jesuits, some of whom even composed abridgments of Descartes' " Meditations." The reputation of Descartes was now so widely extended, that crowds of visitors flocked to see him in his retirement at Eyndegeest near Leyden; but the pleasure which he derived from these attentions was again embittered by the new hostilities of Voetius, who published in 1640, under the name of his friend Schookius, a work entitled, *Philosophia Cartesiana sive admiranda methodus novæ philosophiæ Renati Descartes.* This work was answered by Descartes in his *Epistola Ren. Descartes ad celeberrimum virum D. Gisbertum Voetium, in qua examinantur duo libri nuper pro Voetio Ultrajecti simul editi, unus de confraternitate Mariana, alter de Philosophia Cartesiana.* This reply irritated Voetius to such a degree, that he publicly charged Descartes before the magistrates as guilty of gross defamation; and having suborned five witnesses, Descartes was summoned to appear as a criminal at Utrecht. The French ambassador, however, remonstrated against this conduct to the Prince of Orange, who immediately put a stop to the views of Voetius, whose calumnies and bad conduct were afterwards exposed before a court of justice at Groningen. After having settled a violent dispute with Gassendi, and made a tour through France, for the purpose of visiting his friends, Descartes returned to Paris, where he found complete copies of his *Principia Philosophiæ,* which was published in 1644 by Elziver, and of a French translation of his *Essais,* which had been completed under his own eye by M. de Courcelles. His *Principia* was dedicated to Elizabeth, Princess Palatine, and daughter of the unfortunate Prince Frederic V. This lady was a zealous disciple of Descartes; and not satisfied with reading his works, she went to Eyndegeest to receive instructions from Descartes himself, and made the most wonderful proficiency in her metaphysical studies.

Descartes again sought for tranquillity at Egmond in Holland, that he might apply himself to the study of animals, plants, and minerals; but the ingratitude of his friend Regius, who began to appropriate to himself the discoveries of his master, and who inserted in his *Fondemens de Physique,* a great part of Descartes' Treatise on Animals, which he had seen in MS. was the source of great uneasiness. His anatomical pursuits were in some measure interrupted, by the problem of the quadrature of the circle, which was now agitated among mathematicians, but which he declared to be an useless and an impracticable attempt. In the winter of 1645, Descartes wrote a small tract in reply to Gassendi's *Instances,* and also composed a work on the " Nature of the Passions." In 1646, he conducted a dispute with Roberval, respecting a question of Pappus, and the oscillation of bodies suspended at one of their extremities, and carried on a correspondence with the Princess Elizabeth on moral philosophy.

M. Chanut, the French resident at Stockholm, who had long been the intimate friend of Descartes, applied to him in 1647, as arbiter between himself and Christina Queen of Sweden, on a point in moral philosophy, about which they had differed. In consequence of this application, he wrote a treatise on " Love," with which the Swedish queen was highly delighted. Having returned to France in 1647, the king granted him a pension of 3000 livres, in consideration of his great talents, and of the advantage of his researehes to the human race, and also for the purpose of enabling him to carry on his experiments. After he had again taken up his abode at Egmond, he was ordered by the French court to return to France, with the promise of a new pension, and of an honourable situation, which would not interfere with his researches. The state of public affairs, however, was changed before he reached Paris, and he found that all the promises which had been held out to him could not be fulfilled. He accordingly returned to Holland, where he received an invitation from the queen of Sweden to visit Stockholm, and initiate her into the principles of his philosophy. In October 1649, he arrived in Stockholm, and was received by the queen with that respect and affection which were due from a sovereign who could appreciate his talents. She rose every morning at five o'clock, to receive instructions from Descartes; and she persuaded him to revise and digest the unpublished MSS. which he had brought with him from Holland. In spite of the mean jealousies of some of the Swedish nobility, who envied the attention which he received from Christina, that enlightened sovereign strained every nerve to establish Descartes in her kingdom; and she had repeated conferences with the French ambassador respecting the best method of executing her plans. The delicacy of his health was the principal difficulty which was to be encountered. She proposed to give him an annual revenue of 3000 crowns, and the possession in perpetuity of the property from which it was derived; and lest the climate should be too cold, she agreed that he might reside either in the archbishopric of Bremen, or in Swedish Pomerania. The illness of the French ambassador, however, prevented any arrangement from being completed; and no sooner had he recovered, than Descartes caught a severe cold, which terminated in an inflammation of his lungs, which carried him off on the 11th of February 1650, in the 54th year of his age. Christina was inconsolable for the loss of her illustrious master; she sent for the French ambassador, and expressed her wish to bury Descartes at the public expence, to lay his ashes beside those of the Swedish kings, and to erect a magnificent mausoleum to his memory. The ambassador, however, proposed, that the funeral should be simple, and conducted at his own expence; and his remains were accordingly interred in the cemetery for foreigners, which had been appropriated for Catholics, and children who died before they had the use of their reason. A monument was erected over his ashes, and in a few months afterwards a medal was struck in Holland in commemoration of his brilliant talents.

About 17 years afterwards, M. D'Alibert, treasurer-general of France, conveyed the body of Descartes, at his own expence, to Paris, where it was interred, with great pomp, in the church of St Genevieux du Mont, and a bust in bas relief, with an appropriate inscription, was raised over his grave.

In the personal character of Descartes, we have not to lament any of those vices with which genius is so often allied. If the most unsullied integrity, if piety which was never excited by self-interest, if a constant disposition to forgive his enemies, and live with them in peace, if a contempt of wealth and honours;—if these leading features, united with all the lesser virtues, conspire to form a great character, Descartes, who possessed them all, must stand high in the estimation of posterity. Even the unsettled habits of his life, and the sudden changes from the most sequestered privacy to the bustle and gaiety of a court, never disturbed the tranquillity of his mind, nor engendered any of those habits by which the most virtuous are sometimes ensnared.

His physical and metaphysical writings cannot be viewed in any other light than as ingenious speculations, and the productions of a vigorous fancy; but his optical and his mathematical discoveries, if he had done nothing else, would have entitled him to that immortality which he is now enjoying. In various articles of our work, we shall have occasion to give an account of the leading tenets of the Cartesian philosophy; we cannot, therefore, detain our readers at present with the detail of opinions which must necessarily appear under these articles.

Besides the works of Descartes which we have mentioned, he left the following in MSS.: 1. A Treatise on Man; 2. On the Formation of the Fœtus; 3. On Light; 4. An Explanation of Engines; 5. Letters. All of these, except the Explanation of Engines, were published by M. Clerselier. The two first appeared with the notes of Louis de la Forge; and his Letters were published in three volumes.

Descartes left also several fragments: such as his Treatise on Algebra; Papers on Metals, Plants, and Animals; An Abridgment of Pure Mathematics; Detached Thoughts on the Soul, on Nature, and on the Construction of the Universe. He had also begun a work, entitled, *Studium bonæ mentis;* and another, written in the form of a dialogue, entitled *Recherche de la verite par la lumiere naturelle, qui toute pure et sans emprunter le secours de la Religion ni de la philosophie determine les opinions que doit avoir un honnete homme sur toutes les choses qui peuvent occuper sa pensee.*

DESPOTISM. See GOVERNMENT.

DESSAU, in Latin *Dessavia,* is a town of Germany, in the principality of Anhalt Dessau. It is situated in a delightful plain on the Mulda, at a short distance from its confluence with the Elbe. The streets in the new part of the town are wide and handsome, and the public buildings are elegant. The principal of these are, the palace, the new chancery, the riding school, the hunting house, the bridge over the Elbe, and the cemetery, which is remarkable for its monuments. Besides these, there are two Calvinistic and one Lutheran church, a grammar school, and several charitable foundations. The gymnasium, formerly the philantropinum, which was founded hy Basedow, for the education of boys of good family, has given great celebrity to Dessau. There is also in this town a chalcographick society, and an institution for the education of the Jews. The institution established at Dessau for printing and publishing books on account of the authors themselves, without the interference of booksellers, contributed greatly to the diffusion of knowledge. The most interesting objects in the neighbourhood of Dessau, are the embankment against the Elbe, which is about 60 feet broad at its base, about 10 or 11 feet high, and about 25,016 feet long; and the castle and park of Woerlitz. The principal manufactures are woollen cloths, tobacco, stockings, and hats. Population 7000. See *Wegweiser durch die Scheuswurdigkeiten in Dessau von* Rode Dessau, 1795. (*j*)

DETARIUM, a genus of plants of the class Decandria, and order Monogynia. See BOTANY, p. 221.

DETROIT, a port town of the United States, and principal place of the county of Wayne. It is situated between the lakes Erie and St Clair, on the western bank of the Detroit river. The town consists of several narrow and dirty streets, which run parallel to the river, and are crossed by others at right angles. The foot-paths are formed of square logs, in order to accommodate the passengers in wet weather. The town is encircled with a strong stockade, with four gates, which are defended by block houses. On the west side of the town is a small square fort, with bastions, and a field piece at each corner. The town contains a Roman Catholic church, and a Huron church on the other side of the river, which was formerly devoted to the Huron Indians. There are extensive wooden wharfs for the accommodation of the shipping; and there are no fewer than twelve trading vessels belonging to the town, so that it carries on a very considerable commerce, which consists in exchanging coarse European goods for the furs, deerskins, and tallow of the natives. Number of houses 300. Population 1200. West Long. 82° 56′, North Lat. 42° 40′. (*j*)

DEVAUXIA, a genus of plants of the class Monandria, and order Polygynia. See Brown's *Prodromus Plant. Nov. Holl.* &c. p. 252, and BOTANY, p. 84.

DEVIL. See DEMONIACS.

DEVIZES, a market and borough town of England, in Wiltshire. The town has an elevated situation, Devonshire.

and the buildings are old, and chiefly built of timber and plaster, though several of the houses and shops are handsome. The principal public edifices are two churches, a chapel, and four meeting-houses for dissenters. The ditch, with which the river was inclosed, forms a road round the town, and upon a small eminence within the town, the ruins of its strong castle are still to be seen. The principal manufactures of this place, which are kerseymeres, broad cloth, and serges, employ about 1800 individuals; and a great trade in malt and corn is carried on, by means of the Kennet and Avon canal, which is close to the town.

The following is an abstract of the population return for 1811.

Number of houses	696
Number of families	855
Families employed in agriculture	191
Families employed in trade and manufacture	498
Males	1776
Females	1975
Total population in 1811	3750

(*j*)

DEVONSHIRE, a maritime county in the south-west of England, is bounded on the north and north-west by the Bristol Channel, on the south and south-east by the English Channel, on the west by the county of Cornwall, and on the east by the counties of Somerset and Dorset. It is divided from Cornwall by the river Tamar, and a small rivulet called Marsland-water: The boundaries between it and the counties of Dorset and Somerset are artificial. Its figure is nearly rhomboidal: From north to south it is nearly 70 miles, from east to west about 65, and in circumference about 280 miles. It is reckoned that there are 52 miles on the Bristol Channel, and 82 on the English Channel, in a direct line, not including the prominent headlands and coves or inlets. The shores of Devonshire, on the English channel, are flat, gravelly, or sandy; and this coast, in general, consists of a great number of bays, not deeply incurvated, which are bounded by headlands, composed for the most part of reddish clay or sandstone. The coast on the Bristol Channel is more bold and picturesque. In point of size, Devonshire is the second county in England, being inferior only to Yorkshire. It is reckoned to contain about 1,600,000 acres. It is divided into 33 hundreds, and subdivided into 432 parishes and tythings, besides the 22 parishes which are contained within the boundaries of Exeter. There are in it 40 market towns. It sends 26 members to parliament, two for the county, and two for each of the following places: Plymouth, Exeter, Tavistock, Dartmouth, Ashburton, Barnstaple, Tiverton, Oakhampton, Honiton, Plympton, Totness, and Beeralston. The principal places in it besides these, are Crediton, Biddeford, Axminster, Chudleigh, Cullumpton, Combe Martin, Ilfracombe, and South Molton. Devonshire lies within the province of Canterbury, and diocese of Exeter. It is included within the western circuit, pays one-twentieth part of the land tax, and provides 1600 men for the militia.

Boundaries and extent.

Natural divisions.

Devonshire is naturally divided into the districts of Dartmoor, the Vale of Exeter, South Hams, West Devonshire, and North Devon. Dartmoor stretches across the county, from Exeter to the borders of Cornwall. It is a rushy, naked morass, bounded on the north by bleak hills. In this district, taken in its most comprehensive sense, there are nearly 250,000 acres of open and uncultivated lands; and, what is strictly called Dartmoor, is supposed to comprise upwards of 80,000 of these. The forest of Dartmoor belongs to the Prince of Wales, in his character of Duke of Cornwall; but the outskirts belong to the surrounding manors, many of which have a right of common on the forest, on paying a small sum of money, called *Venville* money. It was originally made a forest by King John, and its boundaries accurately ascertained in the reign of Henry III. Immense masses of granite lie on its surface, which are distinguished by the name of *Tors*. To the north and west of the moor, there are vast tracts of wet swampy ground, which supply the neighbouring inhabitants with peat for fuel. Besides the common peat, a singular species is found, which, when dried and charred, is used by the smiths for tempering their tools. In those parts of Dartmoor where peat is not found, the soil consists of a thin, black, and light mould, lying on a pale, cold, yellow clay, intermixed with sand and gravel. On the higher parts of this district, the soil is of a superior quality, consisting of a good loam. Though Dartmoor forest was undoubtedly covered with wood formerly, at present only a few oaks, of unhealthy appearance and stinted growth, with a few trees of mountain ash, willows, &c. are to be found. The mean height of the forest of Dartmoor, deduced from the trigonometrical survey, conducted by Colonel Mudge, is 1782 feet; and the mean height of the most commanding situations of the county below Dartmoor, by the same survey, was found to be 737 feet above the level of the sea. The Vale of Exeter is a district of a quite opposite character to that which has been just described. It is bounded on the north by the hills that stretch from Clanaborough to Black Down; on the south-east, by the Sidmouth hill, East Down, and Woodbury; on the west, by the mountainous tract of Haldon, and the less elevated hills that lie towards Bow; and by the east by a mountainous ridge, a continuation of the hills that bound it on the north. This district contains about 200 square miles. In the central and southern parts the surface is nearly level, but between Tiverton and Exeter, and Exeter and Cullumpton, there is a good deal of rising ground. The soil of this district varies considerably; but it consists principally of a strong red loam, of uncommon fertility, and of what is provincially denominated *shillet*, a foliated clay, inferior in fertility to the red soil, and extremely liable to be parched in a dry summer. The district of South Hams is the most fertile in Devonshire. It is bounded on the north by Dartmoor, and the high grounds near Chudleigh; on the south by the English Channel; on the west by Plymouth Sound; and on the east by Torbay. It comprises nearly 250 square miles. The northern part of this district is distinguished for its romantic and picturesque scenery. The soil, in general, is a strong red loam, similar to that which is found in the vale of Exeter; the subsoil, a strong clay. The district of West Devonshire is bounded on the east by the Dartmoor mountains; on the west by the river Tamar; on the north by Brent Tor, and the contiguous heaths; and on the south by Plymouth Sound. The appearance of this district is very striking; the vallies in it generally rise with a steep ascent from the banks of the rivulets that divide them, while the hills are rent and broken in a very singular manner. The soil is pretty uniform, consisting of what is called *tilt*, on a substratum of soft, slaty rock or rubble. The district of North Devon is sometimes understood to comprise the whole tract of country lying between Dartmoor and the British Channel,

Dartmoor.

Vale of Exeter.

South Hams.

West Devonshire.

North Devon.

but more commonly it is confined to the country which lies round Biddeford, Barnstaple, South Molton, and the Northern coast. The soil of this district is very fertile, except on the summit of the hills, where it is thin. The surface is greatly diversified, and the scenery uncommonly beautiful.

Climate.

The climate of Devonshire is remarkable for its mildness; the myrtle grows and flourishes even on the shores of the southern coast. On the northern coasts, the weather is sometimes bleak and tempestuous, though even here, about Biddeford and south Molton, the Dutch broad-leaved, double-flowering myrtle, as well as the more delicate, aromatic, and narrow leaved sorts, flourish in the open air, and frequently form part of the garden hedges. In North Devon snow seldom lies for any length of time, except on the summits of the highest hills. About Ilfracombe, vegetation is found to be a fortnight earlier than on the cultivated lands at the foot of Exmoor. From this forest, the north-west winds blow with great keenness in the spring of the year, and the westerly winds from Dartmoor are likewise considered very injurious to the vegetation of that part of the county which is exposed to them. The districts of the vale of Exeter and of South Hams are the mildest and the most salubrious in Devonshire, and are supposed to be more so than any other part of England. The air, too, is much drier than in the other parts of the county, which, on account of its position between two seas, is, in general, too much inclined to moisture.

State of property.

The landed property in this county is very much divided; a large proportion of it being in the possession of respectable yeomanry. The sees of Exeter, York, and Salisbury, the dean and chapter of Windsor, the Universities, and the duchy of Cornwall, likewise possess considerable estates. Land is mostly held by life tenures, the estates being leased out for three lives, nominated by the purchaser. In some parts, however, particularly in the district of South Hams, this kind of tenure is falling into disuse, and leases for 14 years are becoming prevalent. The size of farms varies considerably; but there are very few that exceed 300 acres. The larger farms are provincially termed *Bartons*.

Agriculture.

In the vale of Exeter, wheat, barley, beans, and pease, are principally cultivated on the arable lands; the pasture lands are appropriated to the dairy, except in a few places, where the breeding of sheep and cattle is attended to. In the district of South Hams, the productions of the arable land are the same as those in the vale of Exeter, with the addition of turnips and potatoes. The upper grounds of this district are principally arable; there is, however, some pasture. The lower grounds are almost entirely cultivated as meadows. In the district of West Devonshire, the greater part of the inclosed lands are employed in the convertible husbandry. The system of artificially watering land has been practised here for a great length of time, but on a defective and objectionable plan. *Devonshiring*, or *Denshiring*, as it is more generally called, *i. e.* paring and burning, seems to have originated in this district. In the district of North Devon, wheat and oats are mostly cultivated. Great quantities of cyder are made in the district of South Hams, as well as in that of the Vale of Exeter: the red streak apple is generally preferred for this purpose. Sweet cyder is principally made in the neighbourhood of Haverton; the sweet taste is given to it by its being often racked, which checks the fermentation. The moisture of the climate of Devonshire is supposed to render its cyder more harsh and sour than that of Herefordshire. There is little peculiar in the Devonshire method of gathering fruit for making cyder, except in the circumstance of its being gathered either wet or dry. The Herefordshire press is generally preferred. The fermentation is permitted to go on till the liquor remains quiet, and a candle will burn clear in the bung hole. It is fined by isinglass. A pound being dissolved in about five gallons of cyder, a quart of this liquor is sufficient for a hogshead of cyder. Devonshire is famous for its *clouted* or *clotted* cream. This is made by placing the milk upon a broad iron plate, where it remains exposed to a gentle fire, till the whole of the cream is supposed to have risen to the surface. It is sold by the pound. Much butter is made from clouted cream; but the butter factors at Honiton will not buy butter made in this manner.

Cattle.

The southern boundary of the district of North Devon is justly celebrated for its breed of cattle; they are of the middle horned kind, but vary considerably both in size and form. Their permanent colour is a bright blood red. They are rather below the proper size for working cattle, but they possess great exertion and agility; they are not particularly good for the dairy. The cattle in West Devon are much inferior to those in North Devon; the latter, Mr Marshall supposes to be sprung from the native breed of the island. They are almost universally through the county used for agricultural labour. The Exmoor sheep are found in many parts of Devonshire; they are of the horned middle woolled class, though some are found *polled* or without horns. The Dorsetshire sheep are common in the Vale of Exeter. The native breed of horses resembles the Welsh and Highland breeds, and are very hardy and serviceable.

Rivers.

The principal rivers in this county, are the Taw, the Torridge, the Tamar, the Plym, the Yealme, the Arme, the Avon, the Dart, the Teign, the Ex, the Otter, and the Axe. The Taw rises in Dartmoor, and flows in a northerly direction till it reaches near Chumleigh, when it bends to the west; and receiving the waters of the Moule, it passes Barnstaple, and unites with the Torridge at Appledore. The Torridge rises in a high moor, on the northern part of Cornwall, not far from the Tamar; its windings are very numerous till it reaches the vicinity of Biddeford, where it becomes navigable for boats, and becomes a very rapid river; soon afterwards being joined by the Taw, it proceeds in a north-westerly direction, and falls into the Bristol Channel at Barnstaple Bay. The Dart, supposed to be so called from the rapidity of its current, rises in Dartmoor, and flowing rapidly southwards, passes Totness, after which it spreads into the arm that forms Dartmouth Haven. The origin of the Tamar is near that of the Torridge, not far from the Bristol Channel. It flows southward in a gently winding course, and becomes an arm of the sea at Plymouth Sound. The scenery on the banks of this river, from Plymouth to the Weir, about 22 miles, is uncommonly fine. The Teign rises in Dartmoor. It is composed of two branches, and its course is generally easterly. The country through which it passes is full of rocks till it reaches Bovey Tracey, after which it runs over flat, marshy ground, and falls into the sea at Teignmouth. The Ex, the Isca of Ptolemy, (evidently the same appellation as the Esks, rivers in Scotland, and derived from the Gaelic words which signifies *water*, and which is still retained in the term whisky,) rises in Exmoor in Somersetshire. Leaving this county at Dulverton, it proceeds by Tiverton to Exeter, widening, after it passes

Devonshire.

Topsham, into an arm of the sea, which terminates at Exmouth. The Tavy, the Plym, the Yealme, the Arme, and the Avon, all rise in Dartmoor. The Tavy falls into the Tamar, with which also the Plym unites in forming Plymouth Sound; the other three fall into the British Channel within a few miles of one another.

Roads and canals.

The roads in Devonshire are, in general, remarkably narrow, and by no means either well formed or well kept. Several canals have been projected in this county, but few carried into execution. Among the former, was one from Exeter to Crediton, and another from Barnstaple to Topsham. By a survey taken with a view to this last canal, it appeared that the low water line at Topsham, is 25 feet higher than the low water mark at the bridge of Barnstaple. A canal from the quay at Exeter to Cooley bridge has been lately executed; and one from Tavistock to the Tamar has been completed for some time.

Mineralogy.

The mineralogy of Devonshire presents some appearances worthy of notice. The chalk formation, which, on setting out from London, and going in a direct line from east to west, extends 150 miles, is lost on the road to Axminster, within 4 miles of Honiton. On leaving the chalk district, the transition country commences, of which Exeter may be regarded as the centre. Immediately after losing the chalk and flint, a red sandstone, with an argillo-ferruginous cement, succeeds. About Honiton, it is in the state of coarse-grained gravel; and near Exeter it assumes the character of an arenaceous sandstone. From Exeter, the red argillaceous sand-stone continues for some miles on the road to Plymouth. Near Chudleigh, it is succeeded by a vast number of flint pebbles; and between this place and Ashburton, a blue compact limestone, with numerous veins of calcareous spar, appears. In the neighbourhood of Ivy Bridge, the formation of the slaty and compact grauwacke commences; but on the shore near Plymouth, the cliffs are composed of limestone. The transition limestone, however, in its true character, is found on the left bank of the Plym, at the eastern end of the flying bridge. In ascending the valley of the Arme, the point of termination between the grauwacke and the granite is distinctly seen. The latter forms the primitive rock of the mountain plain of Dartmoor forest. It is a true granite, composed of felspar, quartz, and mica. About three miles from Tavistock, on the road from Twobridge, the grauwacke begins to reappear, in a very distinct manner, at the height of about 1129 feet above the level of the sea. Near the place where the roads join from Plymouth to Oakhampton, and from Tavistock to Twobridge, a bed of greenstone is found in the grauwacke slate; the latter contains more quartz, and becomes less slaty as we approach St Mary Tavy. The height of the line of superposition of the secondary on the primitive rocks, near Cullington, is 700 feet above the level of the sea; at Ivy Bridge hill, 631 feet; in the neigbourhood of Harford Church, Dartmoor forest, 1129 feet; and in the neighbourhood of St Mary Tavy, 648 feet.

Mines.

Tin, lead, iron, and manganese, are found in Devonshire, and also small quantities of gold, silver, copper, bismuth, antimony, and cobalt. Formerly the tin mines were abundant and profitable, now they are scarcely worth the expence and trouble of working. Lead ore is principally of a greyish blue colour. Some rich veins of this metal were discovered at Combe Martin a few years since. They run nearly from east to west, underlying towards the south; they are worked with very little trouble or expence, as they appear just below the surface of the ground. The galena has yielded from 20 to 168 ounces of silver per ton. Near Combe Martin is also found a mine of iron. The principal vein is, in many places, two inches thick, and is said to afford iron equal to that obtained in Wales. Considerable quantities of bog iron are found in the Moorlands. A mine of manganese was formerly wrought near Upton Pyne, but it has been filled up and another opened at Newton St Cyres. The matrix of the ore is the same at both places. The soil is a deep red clay. The deepest part of the mine is about 20 feet. The manganese does not run in veins, but is found in flat, irregular patches. From 150 to 200 tons are exported annually, principally to London. Copper mines are wrought at North Molton, in the parish of Brideston, in the neighbourhood of Tavistock, and at Buckland in the Moor. The mine near Tavistock, called Hawlfriendship, though not more than 23 fathoms in depth, has a rich vein of ore. The country round contains a great quantity of *killas*; and the matrix of the copper is a *caple*. The direction of the mine is from east to west; and the inclination to the north, about 5 feet in a fathom. The ore is generally sold in Cornwall, and smelted in Wales. Antimony has been found in the parishes of Chudleigh, Hennocke, and South Bovey; and cobalt, interspersed with filaments of silver, at Sampford.

Devonshire.

Mineralogy.

Limestone is found in abundance in many parts of Devonshire. In the eastern division of the county, it is soft, like chalk; but in the South Hams, and especially near South Molton, it is hard, with beautiful veins, and admits of a fine polish, so as to be denominated Devonshire marble. The finest kinds of Devonshire marble, however, are found in the district of North Devon. It has been lately much used, and a warehouse opened in London for the sale of it. Gypsum is found in a few places near Plymouth, united with limestone; and in other parts of the lime district, to the south-west of Exeter. About three and a half miles from Upper Pyne, the extraordinary substance, called Thorverton stone, is found. It is dug in a quarry to the depth of 40 feet, and is compact in proportion to its depth. There are three or four quarries all in the same rocks; a calcareous amygdaloid, the nature of which varies considerably. One part of the stratum exhibits an appearance extremely like toadstone. The granules are partly calcareous, partly argillaceous, and partly steatitical. In some places, the nodules are small, in others about the size of a pea. Some parts of the quarry have the appearance of porphyry, others are of a blackish colour, while others are intersected with narrow veins of white calcareous earth. A substance somewhat similar to Thorverton stone is dug out of Heavitree quarry near Exeter, but it is more coarse and loose textured, and approaches nearer to the nature of a breccia; the strata in this quarry are from six to eight feet in thickness, and dip south-east at an angle of about 15°. The stone dug from this quarry, hardens more and more by exposure to the air. The gates and walls, and most of the ancient edifices in Exeter, have been built of Heavitree stone; it is used for coarse millstones for sheeling clover. A kind of slate, called *Holland blues*, is got near East Alwington; and some good covering slates have been found at Lewtrenchard and Werrington. The Black-down hills afford a soft species of sandstone, which is converted into whetstones. A considerable quantity of brown potters clay is raised in the parish of Fremington, and conveyed to Barnstaple and other places, where it is used in the manufacture of the coarser articles of brown or common earthen ware.

Some years ago, a vein of culm was found near Chittlehampton, varying from about four inches to one foot in thickness; dipping to the south-ward about one foot in three. It was wrought for a short time, but the expence being very considerable, it was abandoned. In the extensive flat, called Bovey Heathfield, which seems to have been formerly covered by the tide, and to be below the level of the sea, that remarkable substance called Bovey coal is found. Its strata run nine miles to the southward, keeping to the west of the beds of potters clay in this neighbourhood. The uppermost strata rise to within a foot of the surface, and are from eighteen inches to four feet thick; the lowermost stratum is sixteen feet thick. Between the strata are beds of brownish clay, that diminish in thickness downward. At the bottom of the lowermost stratum of coal, there is also a bed of clay; below this is a bed of sand, and then clay again. The coal retains the vegetable structure, is of a black or blackish brown colour, with very much the appearance of charred wood; light, friable, easily split into irregular laminæ, and strongly impregnated with bitumen. It is divided into two kinds; the stone-coal and the wood-coal; the last has more of the peculiar properties of the Bovey coal than the former. When this coal is burning, a thick heavy smoke, of a fœtid and disagreeable nature, arises from it. The small coal, thrown into a heap, and exposed to the weather, will take fire of itself. Its specific gravity is from 1.4 to 1.558. Its proportion of pure carbon from 54 to 75 per cent. It has been carefully analysed by Hatchett, and his analysis will be found under the article Coal. Among the clay which divides the strata, but adhering to the coal, are found lumps of a bright yellow resinous earth, which is extremely light, and so completely saturated with petroleum, that it will burn like sealing-wax: if the burning is not carried too far, it produces an agreeable aromatic vapour. By analysis, it appears to contain, of resin 55, asphaltum 41, and earthy residuum 3. About two miles from the coal pits, *root* coal, having the form of roots, and *broad* or compressed coal, have been found, as well as in the coal pits. A strong appearance of the trunks and roots of the Scotch fir, may be traced in the *root* coal.

Bovey coal.

Fish.

Devonshire is remarkably well supplied with fish; the Tamar, Tavy, Exe, and Dart, abound in salmon of a peculiarly fine flavour; and the trout of the river Otter are highly celebrated. Besides these, Devonshire is celebrated for soals, plaise, and the John Doree (Zeus-faber). It is said, that the last never made its appearance at English tables, on account of its hideous appearance, till it was introduced by the celebrated epicure and comedian Quin. Another species of the Zeus (Zeus Luna,) is also sometimes found on the coast of Devonshire. This fish, commonly called the opah, or king fish, is not common on the British coast; one of them was taken at Brixham, near Torbay, in the year 1772. It weighed 140 pounds. It was four feet and a half in length, and two and a quarter in breadth, while its thickness was only four inches. The torpedo has been sometimes taken in Torbay, and in the river Dart; and the sepia, or cuttle fish, is not unfrequently caught in the nets of the fishermen off Teignmouth and the neighbouring coast. There are very large oyster-beds, said to cover 100 acres, at Starcross, Topsham, and Lympstone. It appears, by a grant of liberties from King John to the inhabitants of Devonshire, that the wolf was not extirpated at that time in this county; and a passage in Hooker would seem to prove that it existed here even so late as the reign of Elizabeth.

Natural history.

In the lanes leading to the village of Upton Pyne, an uncommon variety of *hieracium umbellatum* is found, which is described by Haller as "H. foliis pene ovatis, vix dentatis, caule humili, pene unifloro." In the neighbourhood of Thorverton quarries, *teucrium scorodonia,* (wood sage,) grows in great abundance, the fruit of which is used by the poor people instead of hops. *Linum angustifolium,* (narrow-leaved flax,) may be truly considered as a Devonshire plant; it decorates the road sides in great luxuriance between Ashburton and Totness. *Valeriana rubra,* (red valerian,) grows in the crevices of the stone of the old castle of Dartmouth; it is not uncommon, in such situations, along the western coast. *Campanula hederacea,* (ivy-leaved campion), is found on some of the large stones, which are sprinkled by the spray of the romantic water-fall of Lidford. *Lichen vulpinus,* with its lemon-coloured threads, adorns the old branches of oak and ash near Hartland priory; a place well worth visiting, on account of its romantic and agreeable scenery. On the shore near Hartland quay, *scilla verna* and *cochlearia danica* are found. On the eastern side of the haven of Teignmouth, there are some rare species of shells, especially *mactra lutraria,* (See Conchology, p. 93.) and *nerita glaucina.* Near Saltash, a species of *turbo* is found, which, though similar to *turbo littoreus,* (the common periwincle,) has some characters that seem to point it out as a different shell; it has a sort of distorted or rude contour, without any appearance of *striæ*; from this, and other circumstances, Dr Maton, who found it, is disposed to name it *turbo rudis.* Its colour is greenish. In the bay of Barnstaple, *asterias papposa,* (the *helianthemoides* of Pennant,) is found. Of the natural curiosities in Devonshire, the Valley of Stones is undoubtedly the most singular and curious. It lies about half a mile north west of Linton. The length of this valley is nearly a mile; its breadth at one end nearly 300 feet, but at the other end much narrower. It is entirely covered with immense masses of stone, thrown together sometimes in the grandest and sometimes in the most grotesque manner. The stones consist of a fine grained argillaceous grit; the fracture is lamellar; and in some instances the texture friable and loose. Some of the masses of rock are completely covered with turf, others are just acquiring a clothing of moss, while others again manifest only incipient traces of vegetation. The rocks between Torbay and Teignmouth have many considerable openings or fissures in them, of which the largest and most remarkable is *Kents Hole.* The depth of this cavern is about 682 feet. The roof of another cavern, which has three entrances, is nearly 30 feet high, and the length of it 130 feet.

Scenery.

There are many extensive and very beautiful views in Devonshire; indeed nearly the whole of the coast along the British Channel presents scenes, grand, picturesque, or beautiful; but the view from Mount Edgecombe is the most celebrated. This place lies near Plymouth, and commands a view, almost unequalled for variety and magnificence of objects. In front, the town and harbour of Plymouth; to the left, the dock yards and fortifications, with ships of various sizes, sailing in and out of the Tamar. On the right, the eye takes in the whole sweep of the channel, with several of the bold headlands, which start out from the coast. If the eye is turned to a nearer prospect, immediately below Mount Edgecombe, appears a fine declivity richly planted, and ornamented with statues, temples, and fountains. The view from Maken heights is still more extensive than that from Mount Edgecombe, but not equal to it in picturesque effect. Powderham castle should also be visited for its pictures, grounds, and romantic views; and the castle of Berry Pomeroy, for its magnificent ruins. Cromlechs, similar to those of Cornwall, are also met with in this county. Devonshire is not particularly distinguished for its manufactures. A few long ells for the East India trade are made at North and South Molton, and some other places. Coarse woollen serges are made at Totness, Moreton, Hempstead, Chagford, &c.; they are generally sent to Exeter to be dyed. At Tavistock, there are an iron foundery and cutlery on rather a large scale. In the neighbourhood of Kingsbridge, a liquor, called *white ale*, is brewed; a material called *grout* is put into it, but the nature of this is not known, except, it is said, to one family. White ale possesses a very intoxicating quality; it is of considerable antiquity, as the *tithe of white ale* is mentioned in the *terrier* of the advowson of Dodbrook. The principal exports from Exeter, &c. are cyder, woollen cloth, potters clay, and a prepared kind of fish called *Buckhorn*. Foreign produce is chiefly brought from London, and coals from Newcastle, Sunderland, and Wales.

Devonshire is esteemed a healthy county; the only endemial disease, is the Devonshire colica, (colic pictonum,) this prevails in the cyder districts, but whether from the solution of lead used in the vessels for making and keeping the cyder, or from ill-made cyder, drank in a recent state, is not known. Many superstitions still linger in this county, among which the most singular is that respecting the Pixies, a race of beings invisibly small, and harmless or friendly to man.

The original name of Devonshire is said to have been Dyvnaint or the country of Glens; the Belgæ had penetrated into it before the arrival of the Romans: in their time, this county and Cornwall were called Danmonium: under them, it was included in the district named *Brittannia Prima*. By the Saxons, it made a part of the kingdom of Wessex; and thus it continued till the incorporation of the Saxon heptarchy into one monarchy.

According to the returns of the population act, in 1811, Devonshire contained,

Inhabited houses	62,318
Families occupying them	79,415
Houses building	766
Houses uninhabited	2,475
Families employed in agriculture	33,044
Families employed in trade, &c.	30,977
Families not comprised in these classes	15,394
Males	179,553
Females	203,755
	383,308
In 1801	354,400
Increase	28,908

DEW. See METEOROLOGY.

DE WITT, JOHN, the celebrated Dutch statesman, was born on the 25th September 1625. His father, James De Witt, was a man of considerable learning and capacity, and held, during several years, the office of burgomaster of the city of Dort.

John De Witt was distinguished, at an early age, by his love of the sciences, and made a rapid progress in his studies. Jurisprudence, political economy, and the mathematics, principally engaged his attention; and he soon exhibited sufficient proofs of his proficiency in the last of these sciences, in his work, entitled, *Elementa Curvarum Linearum*, which was published when he was only 23 years of age. Having finished his academical studies, he took the degree of Doctor of Laws, and afterwards travelled, for some years, in foreign countries. Upon his return, in 1650, he was appointed pensionary of Dort; and after the death of Adrian Paauw, he was chosen pensionary of Holland and West Friesland, intendant of the finances, and keeper of the great seal of these provinces.

The history of the public administration of this distinguished statesman will be given, for the sake of connection, in the article HOLLAND. During nearly 20 years of the most flourishing æra of the United Provinces, he stood at the head of the government of his country; and, by his eminent political talents, contributed to elevate her to a high station among the European powers. By his skilful management, during that period, he contrived to stifle the hopes and pretensions of the Orange party, to preserve a spirit of union among all the provinces, to replenish the treasury, and to equip a fleet which was able to cope with the navy of England.

De Witt was a zealous advocate of peace, and strenuously opposed the war with England in 1652. In the treaty of peace which was concluded with Cromwell, an article was inserted to exclude the Prince of Orange, and his posterity, from the offices of stadtholder and captain-general; an article which excited considerable discontent among the Dutch, and tended to render the minister unpopular. He was, however, reelected pensionary of Holland in 1663. In the war with England, which soon afterwards ensued, he was appointed one of the commissioners to superintend the navy; and he was subsequently joined with two other individuals in the command of the fleet; in which situation he greatly distinguished himself by his gallantry and tactical skill, and received thanks for his services.

In spite of the great talents and influence of the pensionary, the Orange party daily gained new ground; and considerable commotions were excited, throughout several of the provinces, in favour of the young prince. By the *perpetual edict*, enacted by the states of Holland, in the year 1667, no Stadtholder was ever in future to be appointed in Holland; and no Stadtholder of any of the other provinces was ever to have the vote of Holland, at the election of a captain-general of the union. But the measures adopted by De Witt to secure the republican form of government, were entirely disconcerted, in consequence of the invasion of the United Provinces by the French monarch, Louis XIV. The distresses occasioned by the war were severely felt, and the popularity of the minister daily declined. The command of the army was immediately conferred upon Prince William of Orange; and the magistrates throughout Holland were soon compelled by the people to acknowledge him as Stadtholder. The pensionary himself was attacked by four assassins, and left for dead in the streets. At the same time, his brother, Cornelius, was falsely accused of an attempt on the life of the Prince of Orange, and condemned to suffer the question. He endured the most excruciating tortures with an heroic fortitude; and, in the midst of his agonies, repeated, as applicable to his own situation, the well-known ode of Horace, beginning,

Justum et tenacem propositi virum, &c.

The judges were confounded by the unshaken courage he displayed: his life was spared, but he was sentenced to banishment. The pensionary resigned his office, and followed his brother to prison. The mob immediately assembled round the spot, obtained admission into the prison, dragged away the two brothers, whom they inhumanly murdered, and afterwards exercised upon their dead bodies every species of indignity which the fury of the moment could suggest.

John De Witt was unquestionably one of the ablest men of his age. He excelled in bodily exercises, and possessed an intimate knowledge of the liberal arts and sciences. He was a skilful politician, vigilant in his administration, and indefatigably laborious in business. His deportment was modest and serious; and although far from courting popularity by illiberal condescensions, he was, at all times, affable and easy of access. He possessed a firmness and magnanimity of character, which rose superior to difficulties and dangers; an irreproachable integrity, and a disinterested attachment to what he conceived to be the true interests of his country. See *Histoire de la Vie et de la Mort des deux Illustres Freres, Corneille et Jean de Witt*, Utrecht, 1709; and Sir W. Temple's *Remarques sur l'etat des Provinces Unies des Pays-bas*, Utrecht, 1697. DEZIMA. See DISSIMA.

DHALAC, DAHALAC, or DAHLAK, the largest island in the Arabian Gulf, is situated about seven miles from the eastern coast of Abyssinia, between the parallels of latitude 15° 32′ and 15° 5′ north, and the parallels of longitude 40° 3′ and 40° 17½′ east. Its greatest length from north-west to south-east is about 37 miles, and its greatest breadth 18 miles.

The surface of the island is low and flat, without any hills or mountains; and the soil is fixed gravel and white sand, containing shells and marine exuviæ. About three miles to the south-east of Dhalac-el-Kibeer, the rocks rise into a remarkable cliff, not less than 30 feet high. The strata lie horizontally, and are so regular, that they appeared to Mr Salt, even when he was near them, to resemble the walls of an ancient castle. Excepting one or two valleys, where there is some verdure, the island is destitute of all sorts of herbage, but a little bent grass, which affords a meagre sustenance to the goats and antelopes. Large plantations of acacia trees occur in different parts of the island.

The climate of Dhalac differs materially from that of Abyssinia. No rains fall from the end of March to the beginning of October; but in the other months, particularly December, January, and February, there are violent showers, that continue for twelve hours, and fill the cisterns, which supply the inhabitants with water. The following heights of the thermometer were taken by Mr Salt:

January 1807	80°	morning.
——	87	noon.
January 1808	80°	noon.
1808	87	
1809	80	at daylight.
——	90	at night.
1811	82	noon, cloudy.
1812	82¼	
1813	84	

Mr Bruce informs us, that there are 370 tanks or cisterns in the island, hewn out of the solid rock, and capable of supplying with water any British fleet which could be sent into the Red Sea. He supposes that they were erected by the munificence of the Ptolemies, although they are ascribed, by tradition, to the Persians. Lord Valentia has contradicted this statement in the most unqualified terms: "The three hundred and seventy cisterns," says he, "all hewn out of the solid rock, have, after the most minute investigation, been reduced to less than twenty; and of these not one is to be found at Dobelew, where Mr Bruce asserts as an eye-witness, that they are neglected, and open to every sort of animal, and half full of the filth that they leave there, after drinking and washing in them.

This island contains about twelve villages or towns, the principal of which are, Dhalac-el-Kibeer, Dobelew, Gerbeschid, Saied-el-Ait, &c. Dhalac-el-Kibeer was once the principal port in the island, and it still exhibits many marks of its former importance. The town is about half a mile from the sea, and is separated from it by a sloping beach of sand. The harbour is almost surrounded by a chain of nine islands, at the distance of about two miles. On the northern side of it are the ruins of two small stone mosques, with round cupolas at top. A great number of monumental stones are placed erect on the ground around the mosque, and at the head of the tombs to which they belong. Some of them are well carved, and beautifully decorated with flowers, &c. The characters being sometimes in the Cufic, and sometimes in the Arabic, Mr Salt copied several of the inscriptions, which are given in the second volume of Lord Valentia's Travels. One of those stones, which was held in the highest veneration, belonged to the shiek who built the tanks. It is opposite to the principal mosque, and is kept by the natives constantly moist with oil.

About twelve of the tanks at Dhalac-el-Kibeer were nearly of the same construction. One of them was square and uncovered, and the largest would hold about 150 tons. They were excavated from the solid rock, and were chunamed, but not lined with stone. In another tank the roof was supported by five pillars. Its longest diameter was 24 feet, its shortest 22, and the pillars were six feet in circuit, and the interval between each was six feet; but some of the pillars were two feet, and others four feet distant from the wall. They had no distinct capital, but were thickest at the top. This tank was thirteen feet deep, and the whole was covered with chunam.

The village of Dobelew is fully as large as Dhalac-el-Kibeer. It has a white tower at the east and west ends, and two of a smaller size on the north. Bruce says, that it consists of 80 houses, covered with bent grass, built of calcinable stone, brought from the sea. The harbour, which is three miles north-east of the town, is represented by Bruce as having a circular form and a narrow entrance, but full of rocks, consisting of ramifications of white coral, intermixed with large black stones. Lord Valentia, on the contrary, Dhalac.

observes, "that the round harbour of Dobelew, and its narrow entrance, are no where discoverable; and the town itself, instead of being three miles S. W. of the harbour, is, in fact, on a parallel with the northern extremity of Irwee, which forms the harbour, and is an island."

At the distance of four and a half miles from Dobelew stands Gerbeschid, which consists of about twenty wretched huts, about three miles distant from the sea. A considerable quantity of cheese is exported from this place to Loheia. The island of Irwee contains a small village, which is visited by fishermen in catamarans. The coast is low, with a few trees scattered up and down; and the sea between it and Dobelew is shallow, and full of shoals.

The inhabitants of this island are a simple and an inoffensive people, and are employed almost solely in working the vessels, which trade to the different parts of the coast. Fish is the principal source of their subsistence; and in some of the villages, which are not visited by the Arabian boats, the inhabitants will sometimes live a whole year without tasting bread. The women are excellent fishers. They have, in general, a brown complexion, but are sometimes of a reddish hue, a little darker than the colour of new mahogany. The language of the inhabitants is that of the "Shepherds," though Arabic is also generally spoken.

Dhalac is dependent on Massowah. A goat brought every month from each of the twelve villages constitutes the principal part of the revenue of the governor. Every Arabian vessel also brings him a dollar or pataka; and every vessel from Massowah contributes a pound of coffee. Venetian glass beads are the only money current in the island.

Dhelly || Dial.

The valuable fisheries for pearls and tortoise shells, which were formerly carried on in the Red Sea, extended from Dhalac to nearly the latitude of 20°; and the divers and fishers were principally obtained from that island. Under the Ptolemies, it was successfully carried on. It was afterwards rented to the Basha of Suaken; but when it became dependent on the Basha of Jidda, the Aga, whom he appointed, appropriated to himself the provisions and salary which were allotted for the fishery. The pearls found here are of the largest size, and of the finest kind; and the tortoise shells, which were carried to the East Indies and China, were esteemed the finest in the world. See Bruce's *Travels in Abyssinia*, vol. i.; and Lord Valentia's *Voyages and Travels*, vol. ii. chap. i. and v. (π)

DIADELPHIA. See BOTANY, p. 76. and 272.

DIALIUM, a genus of plants of the class Diandria, and order Monogynia. See BOTANY, p. 90.

DIAL, an instrument generally so constructed as to show the hour of the day by the solar shadow of some opaque body falling on a system of lines traced on a surface. Sometimes the surface is a horizontal plane, and then the instrument is called a *horizontal* dial. The surface of a dial, however, may be of any figure whatever, and may have any position; and hence the various kinds of dials, as *horizontal, vertical, polar, equatorial,* &c. the principal of which will be found explained in the article DIALLING. (ξ)

DIALLING.

History.

1. DIALLING, or the method of constructing sun dials, is a branch of mixed mathematics, which depends partly on the principles of geometry, and partly on those of astronomy.

Definition.

This branch of mathematical science was called by the Greeks and Romans *Gnomonica*, also *Sciaterica*, from Γνώμων *an index*, and σκία *a shadow*. It has also been called *Photosciaterica* from φως *light*, and σκία *a shadow*, because the hour is sometimes indicated by the light of the sun, as when it passes through a small hole, and falls on the dial. Again, it has been called *Horographia*, because it is the art of writing the hours; also *Horologiagraphia*, because sun dials were formerly called *Horologia*; they were also named *Sciaterica*.

History.

2. As the division of time is a matter of great importance, this branch of knowledge must have early engaged the attention of mankind. It appears that the ancient Jews had instruments for measuring time by shadows; for it is recorded in scripture, 2 Kings, chap. xx. and Isaish, chap. xxviii. that, by a miracle, the shadow went back ten degrees on the sun dial of Ahaz, as a sign given to Hezekiah that he should recover when he was "sick unto death." This happened 113 years before the Christian era.

3. The nations of antiquity differed greatly from us in their mode of reckoning time; we know, that first the rising and setting of the sun were the circumstances which determined the length of their day. The Babylonians began the day at sunrise, and reckoned it to continue until the next following sunrise. The Athenians, again, considered the interval between any sunset and the next following, as forming their day, which they divided into two portions; the natural night extending from sunset to sunrise, and the natural day from sunrise to sunset. It is probable that the Egyptians reckoned time in the same manner; but as they cultivated astronomy long before the Greeks, they must have earlier felt the inconvenience of this manner of reckoning time, and thence have been led to begin the day at noon.

History. Origin of dialling.

4. The Egyptians and Babylonians were the first that could determine correctly the position of the meridian. The former have shewn their skill in resolving this problem, by placing the pyramids in the direction of the cardinal points; they are also reckoned to have been the first who divided the day into 24 equal parts: but it is certain that they were one of the earliest people who divided the duration of the day into equal parts, whether astronomically or mechanically, and this was long before the Greeks had reached the same degree of refinement in reckoning time. Although this last nation employed the word Ὥρα from the remotest antiquity, yet it did not indicate a division of the day, but a season, an indeterminate portion of time. Until the period that philosophy was cultivated among them, the only circumstances of the day that they noted, were the rising and setting of the sun, and the time of noon found vaguely, as by the light of the sun falling upon, or leaving the face of some edifice. As to midnight, it could only be determined by a rough estimation.

5. When Greece became enlightened by philosophy, geometry, and astronomy, this last science furnished

History.

the means of dividing time with more accuracy. The first step was doubtless the astronomical determination of noon; an invention which Diogenes Laertius has attributed to Anaximander, the successor of Thales, who erected a gnomon or pyramid, about 600 years before the Christian era. This instrument shewed the time of noon, either by the shortest shadow, or by its falling on a meridian line. It is probable that Anaximander received this invention from his master Thales, who may have learned it in Egypt, where he studied. Pliny has given the merit of it to Anaximenes. Certainly one or other of these philosophers gave the first sun dial to the Lacedemonians; and as the progress of discovery is, in general, slow, it may be that all the three may have had some share in the invention.

Origin of dialling among the Greeks.

6. Herodotus, however, gives a different account of the origin of dialling among the Greeks. According to him, they received the *Pole*, and the *Gnomon*, and the division of the day into 12 parts, from the Babylonians; and this accords very well with what is stated by other ancient writers, namely, that Berosus, a Chaldean, founded a school at Cos, where he taught the sciences cultivated in his own country. Vitruvius attributes the construction of a kind of dial to a philosopher of this name; and it was probably he that taught to the Greeks the construction of sun dials, and the division of the day into 12 parts. Certain circumstances render it probable that this philosopher lived nearly 540 years before Christ, or about the time of Anaximander and Anaximenes.

7. The manners of the Romans appear to have been but little favourable to the cultivation of the mathematical sciences, and accordingly it was late before that nation adopted any thing like a tolerably accurate method of dividing time. Even in the middle of the fifth century, after the building of Rome, the only periods of the day noted, were the rising and setting of the sun, and mid-day; which last was proclaimed by a herald when he saw the sun from the senate house, between the *Rostra* and a place named *Græcostasis.*

Roman dials.

It has been said that the first sun dial known at Rome was placed near the temple of Quirinus, by the directions of Lucius Papirius Cursor, about the year of the city 460, in order to fulfil a vow made by his father. However, Pliny, who relates this circumstance, doubts it; and shortly after states that the first sun dial was set up near the *Rostra*, about 30 years later, during the first Punic war, by the consul Valerius Messala, who brought it from Catania in Sicily after the taking of that city. This dial, however, measured time imperfectly, because it was made for a latitude considerably different from that of Rome. Yet it was used for a period of 99 years; and at last the consul Martius Philippus, about the year of Rome 590, caused another more exact to be constructed, probably by some Greek, for the Roman arms had then penetrated into Greece. The Romans, however, were still without the means of measuring time in cloudy weather and during the night, until about a century afterwards, when Scipio Nasica procured a *Clepsydra* to be constructed, which was perhaps also the work of some Greek; for Hero and Ctesibius, who lived under the first Ptolemies, were the inventors of this ingenious machine.

8. Sun dials, or *Horologia*, are frequently mentioned in the writings of antiquity. Menander has introduced into one of his pieces, a hungry parasite who had watched on a dial the arrival of the shadow at the hour of a repast; but in his eagerness, he had begun so early as to mistake the light of the moon for that of the sun. It is related, that a sun dial having been shewn to Epicurus, he exclaimed, "What a fine invention to hinder us from forgetting to dine!" The Greek anthology has preserved a humorous inscription placed on a sun dial, the meaning of which is, that *six hours of the day are given for labour, the remaining four say to mortals, live;* these hours being marked on the dial by the Greek letters Z, H, Θ, I, which may be supposed to form the word ZHΘI, *live.*

9. Aulius Gellius has preserved, in his Attic Nights, a curious fragment of a comedy of Plautus, in which a parasite exclaims against sun dials in these terms:

> "Ut eum dî perdant, primus qui horas reperit,
> Quique adeo primus statuit hic solarium,
> Qui mihi comminuit misero articulatim diem.
> Nam me puero uterus erat solarium.
> Multo omnium istorum optimum ac verissimum:
> Ubi iste monebat esse nisi cum nihil erat:
> Nunc etiam quod est, non est, nisi soli lubet.
> Itaque adeo jam oppletum est oppidum solariis,
> Major populi pars avidi reptant fame."

"May the gods confound the fellow who first invented hours, and placed the dial here, which doles out the day piecemeal to me, an unhappy wretch! For when I was a boy, my belly was my dial, and it was by far the best, and truest of them all: I ate whenever it warned me, that is, if any thing could be had; but now, whatever there may be, it is not, unless forsooth it pleaseth the sun: Indeed, since the town was filled with dials, the greater part of the people crawl about starving with hunger."

10. Modern dials, in general, indicate the hour by the position of the shadow on a plane; but there is reason to suppose, that some of the ancient dials shewed the hour by the length of the shadow; and that even the human body was made, in this way, to serve the purpose of a dial. This mode of determining time, however, had the inconvenience of requiring a table of numbers, to shew the length of the shadow at every hour for different times of the year. An ancient calendar has been preserved by Palladius, a writer of the sixth century, which contains a table of this kind, shewing the length of the shadow for every hour of the day at the end of each month.

Ancient dials.

11. Vitruvius has preserved, in his writings, the only notices that have come down to our times respecting the different kinds of ancient sun-dials, and their inventors. According to him, Berosus the Chaldean was reputed the inventor of the dial called *Hemicycle*, hollowed into a square, and adapted to the climate. Aristarchus of Samos invented the *Scaphe*, or hemisphere, as well as the *Discus*. Again, Eudoxus of Cnidus, or, according to others, Apollonius, contrived the *Arachne*, or *Aranea*: Scopas of Syracuse made the *Plinthium*: The *Pros-ta Istoroumena* was the work of Parmenion; and the *Pros-panclima* that of Theodosius and Andreas: Patrocles was the inventor of *Pelecinon*, or *Bipennis*: Dionysidorus of the *Cone*, and Apollonius of the *Pharetra*. He enumerates the names of other dials, viz. the *Gonarche*, the *Engoniaton*, and the *Antiboreum;* and we also learn from him, that there were portable dials (*viatoria pensilia*), concerning which different authors had written, and the description of which, he says, depends on the *Analemma*, which he had previously described.

Aristarchus' dial.

12. Of these dials, that of Aristarchus probably was the most simple. It was a hemisphere cut in a cubic

History.

block of stone, having its base horizontal. At the bottom of the cavity, a style was erected, the top of which was at the centre of the sphere. It is easy to see that the summit of the style would describe every day an arc of a circle at the bottom, similar to the diurnal parallel described by the sun. The equator and tropics would be easily delineated on the inside of the hemisphere, and these being divided into twelve equal parts, curve lines drawn through the divisions would be hour lines, and would divide into 12 parts the trace of the style, and the entire day from sunrise to sunset. Several antique dials of this kind have been found; the first in 1741, in the ruins of an ancient Roman house, situated on Tusculum, which appears to have belonged to Cicero, so that the dial is valuable both on account of its antiquity, and its having belonged to the Roman orator, who seems to have referred to it in one of his letters to his freedman Tiro. It was placed in the museum of the Roman college, and described in 1746 by P. Zuzzeri, a learned jesuit. We have given a figure of it in Plate CCXXVIII. Fig. 1; and it may be remarked, that the useless part of it has been cut off by a plane parallel to the equator and the tropics of the dial. This plane has been found to be inclined to the earth's equator at an angle of 48° 17′ or 18′; now this is precisely the inclination of the horizon of Tusculum to the equator, which shews that the dial has been made by an intelligent person.

Cicero's dial.

Plate CCXXVIII. Fig. 1.

A dial of the same construction was discovered in 1751, at *Castel-Nuovo*, in the ecclesiastical state, and was placed by Pope Benedict XIV. in the museum of the capital; and another was disinterred the same year about the same place. These exhibit in their cavity not only the hour circles, but also the equator and the tropics. A third was found in the ruins of Pompeii, but this differs from the others in having only the hour lines and equator.

13. The figures of some antique dials have been preserved on the monuments of antiquity. Gabriel Simeoni has described one which accompanied a calendar. It was a triple dial, the middle one traced on a concave cylindric surface, and the two lateral ones on plane surfaces. There was formerly a dial at Ravenna, which had the figure of a hemisphere supported on the shoulders of a Hercules: it was turned towards the south. Lambecius has also preserved the figure of a dial supported on a column. He copied it from a very ancient manuscript in the imperial library. It wants the upper part of the hemisphere, which would have been useless, because the shadow of the extremity of the stile passes only over the inferior part.

14. A very curious portable dial was dug out of the ruins of Portici in 1755, and described in the preface to the third volume of the description of representations found in the ruins. Its shape is that of a bacon ham; and it is suspended to a ring fastened to the leg. The end of the tail, which has been preserved, serves as a stile. Its figure is shewn in Plate CCXXVIII. Fig. 2. The hours are marked on that part of the surface which is nearly plane. There appears to be seven vertical lines intersected by as many others, and below these intervals the names of the months are written. Such as understand dialling will readily see how this dial is to be used. It must be suspended by the ring, and turned slowly round, until the shadow of the top of the stile fall upon the line of the month, the hour will then be indicated by the nearest transversal line.

Plate CCXXVIII. Fig. 2.

15. The theory of sun dials must have been cultivated among the Arabians along with the sciences of mathematics and astronomy, upon which it depends, during the period when Europe was enveloped in the darkness of ignorance; and some manuscript treatises of their astronomers on this subject are to be found in the repositories of literature. In the Bodleian library, there is a treatise on sun dials by Takioddin Ibn Marysh, who lived about the year 1579; and it contains others by Abul-Hazen de Maroc and Mohalled. Their celebrated philosopher Jacob Alkendi, has also written on shadows; and it was probably a treatise of his on sun dials that was called *Sciotherica.*

History.

The necessity of a method of dividing time, has induced even the Turks to attend to this subject. One of their astronomers, Mustapha ben Ali, who lived about 1533, has written a treatise on sun dials, and the division of time.

16. Upon the revival of learning in Europe, the science of gnomonics was again cultivated, and treatises were composed on the subject by John Stabius, Andrew Stiberius, and John Werner, astronomers of the 15th century; but they have remained in manuscript. To these may be added John Schoner, an astronomer of the beginning of the 16th century, who published in 1515 a work called *Horarii cylindri canones,* where he teaches the construction of cylindrical dials. His other gnomonical works were afterwards published by his son. Other early writers on this subject, were Munster and Orontius Fineus. The first of these published at Basil in 1531, a work called *Compositio horologiorum in plano muro,* &c. and the latter brought out in 1532, his work *de Horologiis solaribus et quadrantibus,* libri iv. Among the gnomonists of that age may be rekoned Vinet and Bullant, who have written in French. The Chartreuse John Bat. Vico Mercati, who lightened his solitude by writing his treatise *Degli horologi solari.* Commandinus, whose work is called *de Horologiorum descriptione,* and who afterwards published an edition of the *Analemma* of Ptolemy. Maurolycus, whose treatise *de Lineis horariis* appeared in 1575. Paduanus of Verona *de compositione et usu multiformium horologiorum.* Valentino Pini, J. B. Beneditti or de Benedictis, who published a treatise *de Gnomonum umbrarumque solarium usu* 1574; and Clavius the jesuit, whose *Gnomonices, libri viii.* appeared in 1581 and 1599.

17. The Portuguese astronomer Nonius, deserves to be mentioned here, on account of his having noticed and explained the phenomenon of the retrogradation of the shadow on a dial in certain latitudes. Some have supposed that it was in this way the shadow went back on the sun dial of Ahaz, but this explanation seems quite inadmissible.

18. The 17th century produced a multitude of works on dialling in all languages, and suited to all capacities, from the geometer, who required merely the theory in order to see at once all its applications, to the stone mason, who, ignorant of its principles, could only follow practical rules. The principal writers of this age were Muzio Oddi *Degli Orologi Solari* (*Mil. & Ven.* 1611 and 1638, in 4to.); Kircher, *Ars magna lucis et umbræ*; P. Maignan, *Perspectiva horaria,* lib. iv. (Rome 1646 in fol.); Deschales in his *Cursus Math.* (Ludg. 1674 and 1690, in fol.); Forster, *The art of dialling,* &c. (Lond. 1638, in 8vo.); Collins' *Description and use of a great universal quadrant,* (Lond. 1658); Desargues, *La methode de Gnomonique,* (Paris 1641, in 4to.); De la Hire, *Gnomonique,* (Paris 1681, in 8vo.); Ozanam, *Gnomonique,* (Paris 1673, in 8vo.); Wells'

Art of Shadows, (Lond. 1635); Leybourn, *Dialling, Plane, Concave, Convex, Projective, Reflective, Refractive*, &c. (second edit. Lond. 1700, fol.)

Among the writers of the last century, we have Don Bedos de Celles, *Gnomonique Pratique*, (Bord. 1750, in 8vo.); Gruber, *Horographia trigonometria*, (Prag. 1718); Rivard, *Gnomonique*, (Paris, 1742, in 8vo.); Casbroni *Horographia Universalis*, (1730); Leadbetter, *Mechanic Dialling*; W. Jones, *Instrumental Dialling*; Emerson, *Dialling*, (1770, 8vo.); Hutton's *Translation of Montucla's Mathematical Recreations*, vol. iii. (1803); Dr Brewster's edition of Ferguson's *Lectures*. Writers on the sun dials of the ancients, are Zuzzeri, *D'un ant. villa scopertu sub doso del Tusculo ed un antico orologio a Sole tra le ruinæ della ritrovato*, (Venez. 1746, in 4to.); George Henri Martini, *A treatise concerning the Sun Dials of the ancients*, (in German); and Ernesti *De Solariis*. Some have composed tables, in order to abridge calculations on dialling. In this class of writers may be reckoned Hyppolite Saladio, *Tabulae Gnomonicae una cum earum usu et fabrica*, (Rom. 1617, in 4to.); Dominico Lucchini, *Tratenimenti mathematici*, (Rom. 1630, in 4to.); Grov. Lud. Quadri, *Tavali gnomoniche*, (Bol. 1733, in 4to.); the Prince Caraffe della Roccella, *Exemplar horologium solarium civilium*, (Mazzareni 1686, an enormous folio.)

The theory of dialling has sometimes been treated as a branch of perspective, as by Sgravesand in his *Essai de Perspective*, (Amst. 1711, in 8vo.); and Dr Horsley in his *Tracts on the Projection of the Sphere*, (Oxford, 1801, in 8vo.) The subject has also been treated as a branch of Analysis by Kaestner in his *Gnomonica Universalis Analytica*, (1754, Lip. in 4to.); M. M. Dionis du Sejour and Godin, in *Recherches Gnomoniques les regradations des planetes et les Eclipses du Soleil*, (Paris, 1761, in 8vo.)

Of late, the French mathematicians have referred the theory of dialling to what they call *Descriptive Geometry*; and in this way the subject has been treated by Hachette in his *Cours de geometrie descriptive*; Lefrançois in *Journal d'Ecole Polytechnique* IIe *Cahier*; and Berroyer in his *Gnomonique ou theorie des cadrans solaries*, given among the additions to the second edition of Biot's *Astronomie Physique*, tom. iii.

In the following treatise, we shall, in general, explain the principles of this theory, and the construction of dials, in a manner strictly geometrical. As, however, there may be some of our readers who wish to make dials, and yet are not sufficiently skilled in geometry to comprehend fully the theory, we shall give practical rules for delineating the most useful kinds, employing only the common problems of elementary geometry.

The General Principles of Dialling.

General principles of dialling.

19. The principles of astronomy teach us that the earth moves in an orbit about the sun, and completes a revolution in a year; while, at the same time, it revolves uniformly from west to east on its axis, which, although it changes its place, is yet always parallel to a fixed imaginary line, called the axis of the world. By the first of these motions, the sun appears to move round the heavens, completing a revolution in the course of a year; and by the second, the sun, and all the heavenly bodies, have an apparent diurnal motion about the earth from east to west.

20. The motion of the earth in its orbit is not equable; and hence it happens, that the apparent motion of the sun in the heavens is not quite uniform: besides, the plane of that motion does not coincide with the plane of the diurnal motion. On these two accounts, the apparent diurnal motion of the sun differs a little from uniformity, as is particularly explained in Astronomy, p. 652.

21. In the theory of dialling, however, we are to suppose that the sun's diurnal motion is always perfectly uniform, and that it moves throughout the day in a circle parallel to the equator; but as neither of these hypotheses is strictly true, the time of the day shewn by a dial will in general differ from that shewn by an accurate clock. However, the difference admits of exact estimation, and tables have been calculated which shew its amount for every day throughout the year. See Astronomy, p. 653.

22. In constructing dials, it is also usual to leave the effect of refraction out of consideration; its effect might indeed be exactly appreciated, and tables formed by which the time indicated by the dial might be corrected; or the dial might even be so constructed as to give the time cleared from the error. But this would be a degree of refinement which may very well be overlooked in the practice of what, since the invention of clocks and watches, is now little more than a scientific recreation.

23. If the earth's radius had any sensible proportion to its distance from the sun, that ought to be taken into account in the construction of dials. But the earth is almost a mere point, as seen from the sun; and hence it happens that the diurnal motion of the sun about any line on the earth's surface, which is parallel to its axis, may be accounted uniform, exactly as if it were performed about the axis itself.

24. To understand the nature of a dial, let us suppose that *e*EF (Fig. 3.) is a straight rod or wire, parallel to the axis of the earth; or which, if produced, would pass through the pole of the heavens; and let us suppose that one of its extremities terminates at *e* in a plane, *a b c d* having any position whatever. Let us farther suppose, that the wire passes through E, the centre of a circle ABCD, described on some solid substance, and that it is perpendicular to the plane of that circle: Then, as the wire passes through the poles of the heavens, the circle ABCD will be parallel to the terrestrial equator, and it will be in the plane of the equinoctial circle in the heavens, because on the earth's surface any plane whatever, parallel to the equator, may be considered as coincident with it, when produced to the celestial sphere. Plate CCXXVIII. Fig. 3.

Now, because the axis of the earth is perpendicular to the plane of the circle which the sun appears to describe in the heavens by his diurnal motion, and passes through its centre, and that the same is almost exactly true of every line parallel to the earth's axis; when the circle ABCD is illuminated by the sun, the wire EF will project a shadow upon it, which will revolve about E as a centre, passing over equal arcs of the circumference in equal intervals of time. If, therefore, we suppose the circumference of the circle to be divided into 24 equal parts, and the points of division to be numbered 1, 2, 3, 4, &c. to 12, and again 1, 2, 3, 4, &c. to 12, as in the figure, and the circle to have such a position, that the shadow falls upon E 12 at noon; then, at one o'clock, it will have the position E 1; at two o'clock, it will have the position E 2; at three, the position E 3; and so on. In short, the hour of the day, from sunrise to sunset, will be indicated by the shadow, just as it is shewn upon a watch by the motion of the hour hand. And as we suppose the motion of

Theory.

the sun to be quite uniform, the shadow will always have the same position at the same hour every day throughout the year.

25. If the two planes ABCD, *a b c d* are illuminated at once by the sun, the rod *e* EF will project a shadow on them both. Let us suppose that at the instants the line EF projects its shadow in the directions of the lines E 12, E 1, E 2, &c. on the upper plane, the shadow of *e* E falls in the lines *e* 12, *e* 1, *e* 2, &c. respectively on the lower plane; and let other cotemporaneous positions of the shadows be found for every hour the sun can shine on the planes; then, as the shadow will always come to the same position on each plane at the same hour of the day, the hours will be indicated also by the shadow on the plane *a b c d e*.

26. Each of the planes ABCD, *a b c d* is a *dial*: we have supposed the upper plane to be perpendicular to the axis of the world; and in this particular position, the shadow will describe equal angles on it in equal times. The plane of the dial may, however, have any position; but if it is not perpendicular to the earth's axis, the motion of the shadow projected on it will not be uniform, as it is on the plane of the equinoctial.

27. The rod EF, which projects the shadow, is called the *Style*; also sometimes the *Axis* of the dial.

The lines E 12, E 1, &c. which indicate the position of the shadow at the different hours, are called *Hour Lines*. The hour lines are evidently the common section of the plane of the dial, and a plane passing through its axis and the sun.

The point in which the axis of a dial meets its plane, which is also the common concourse of the hour lines, is called its *Centre*. There are other technical terms belonging to this subject, but these we shall explain as we proceed.

28. The latitude of the place for which a dial is to be made, is an important element in their construction. This may be known by good maps, or it may be determined by astronomical observations, as is particularly explained in our article Astronomy, p. 665.

How to trace a Meridian Line on any Plane.

Method of drawing a meridian line.

29. In constructing a dial, it is always necessary to determine the line in which the plane of the meridian meets the plane of the dial. If the plane of the dial is not horizontal, it will be convenient, in the first place, to trace a meridian line on a horizontal plane near it. In our article Astronomy, p. 653, we have explained one way of doing this, by two equal shadows of a pin perpendicular to the plane. A meridian may also be found by any three shadows of an upright pin or style. Let OV (Fig. 4.) be the style which stands at right angles to the plane in O, and OA, OA′, O′A″ its shadows at three different times of the day. Then, if AV, A′V, A″V be joined, the angles AVO, A′VO, A″VO are the sun's distances from the zenith at the times of noting the positions of the shadows; and these are known, because in the right angled triangles AOV, A′OV, A″OV, the sides about the right angles at O are known, from which the angles at V may be found.

Plate CCXXVIII. Fig. 4.

Let us now suppose that the sphere is projected stereographically on the horizontal plane AA′A″, so that O is the centre of the primitive, the eye being in the nadir, then the lines AO, A′O, A″O produced will be the projections of azimuth circles; if the projections of the sun's places, in these circles, at the times of observation, be now found, a circle traced through them will evidently be the projection of the circle of declination, which the sun describes in the heavens that day; and the position of the meridian may now be found, because it will pass through the centre of that circle, and O, the centre of the horizon. Hence we derive the following construction.

Theory.

Make three right angled triangles AOV, A′OV, A″OV, (Fig. 5.) which have each VO=VO, in Fig. 4. the height of the style; and bisect the angles at V, by the lines V*a*, V*a*′, V*a*″. Produce the shadows AO, AO′, AO″, so that O*a*, O*a*′, O*a*″ of Fig. 5. may be respectively equal to O*a*, O*a*′, O*a*″ of Fig. 4. Describe a circle through the points *a*, *a*′, *a*″, and from X its centre, draw a line through O; this will be in the direction of the meridian. For by the principles of the stereographic projection of the sphere, if we take the horizontal plane A, A′, A″, for the plane of projection; the lines O*a*, O*a*′, O*a*″, will be the projections of circles passing through the zenith and the sun, at the times when the shadows have the positions OA, OA′, OA″; and as by construction, O*a*, O*a*′, O*a*″ are the tangents of half the zenith distances AVO, A′VO, A″VO, the points *a*, *a*′, *a*″, are the projected places of the sun; and the circle *a*, *a*′, *a*″, is the projection of the parallel it describes in the heavens on the day of observation, and OX, which passes through its centre, is the projection of the meridian. See Projection of the Sphere.

Plate CCXXVIII. Fig. 5.

30. We may even find the latitude of the place of observation: For if P, the projection of the pole of the circle, be found, then OP will be the tangent of half the distance of the pole from the zenith, (OV being taken as radius,) that is, the tangent of half the complement of the latitude.

30. In this construction, no allowance is made for refraction, or change of declination. The zenith distances may, however, be corrected for refraction by the proper tables: (See Astronomy, pages 660 and 799.) And if the observation be made on the solstitial days, the error from change of declination will hardly be any thing. This method of tracing a meridian line was proposed by a very old author on dialling, named *Mutio Oddi da Urbino*, in a work called *Gli Horologi Solari Nelle Superficie piane*.

31. Another method of tracing a meridian line is, by observing when two stars which have the same right ascension, or whose right ascensions differ by 180°, come into the same vertical plane; for then they are both on the meridian. The observation may be made by means of a plane surface, kept in a vertical position by its own weight, or by any other suitable contrivance, and which is moveable about a vertical line. The pole star and the first ε of the tail of the *Great Bear*, are applicable to this purpose. In the beginning of 1811, their mean right ascensions were,

Star ε, ...	191°	25′	3″
Pole Star, ...	13	41	41
	177	43	22

This difference, although not exactly 180°, is yet sufficiently near; because when ε is on the meridian, the arc of 2° 16′ 38″, by which the pole star has advanced in the small circle it describes, subtends an angle of about 4′ only. The stars α of *Ophiuchus*, and β of the *Dragon*, are well adapted to the same purpose, the right ascensions and declinations are,

	R. Ascen.	Declin.
α of Ophiuchus, . .	261° 32′ 26″	12° 42′ 29N″.
β of Dragon, . . .	261 32 33	52 26 47N.

Theory.

As these have almost the same right ascension, and differ 40° in their declination, they are very proper for determining the position of the meridian.

32. In whatever way a meridian is traced on the horizontal plane, it should be quite adjoining to the plane on which the dial is to be delineated; and it ought to be so placed, that a vertical plane passing along the meridian line, may cut the dial at the point where the axis is to be fixed. To take a familiar example, we shall suppose that the dial plane is a vertical wall carefully smoothed and verified with a rule and plumb-line; and this being understood, it will be easy to suit the operation to any other plane.

Plate CCXXVIII. Fig. 6.

Let BC (Fig. 6.) be the meridian line on a horizontal table, and *tn*, *sq*, two plumb-lines, which descend on the meridian line from a horizontal rod that has one end fixed in the wall, and the other supported on a stand. If the table admits of being pierced with two holes, the plumb-lines may with advantage pass through them, and the plummets hang suspended in vessels filled with water. They will thus be more steady, and more easily adjusted. The eye is now to be directed towards the wall, so that the visual ray may be in the plane of the plumb-lines; and then the line AK upon the wall, which they both appear to cover at once, will manifestly be the intersection of the plane of the meridian, and the plane of the dial; and consequently will be the twelve o'clock hour line. A point A is now to be assumed, as the centre of the dial; and the axis AC must be fixed in the wall in such a position, that it may lie in the plane of the threads *tn*, *sq*, and make with a horizontal line AD, an angle equal to the latitude of the place, or with CR, a vertical line, an angle equal to the co-latitude; and then it will manifestly be parallel to the axis of the world.

33. The stile may have any shape that admits of its being firmly fastened to the dial; and before it is fixed, it may be convenient to fasten a piece of wood to the wall, so that it may have a plane surface exactly in the plane of the meridian, as indicated by the plumb-lines, and a line traced on its surface in the position of the axis or edge of the stile; this board will serve to support the stile in its position, until it be fastened either with its plane in the plane of the meridian, or perpendicular to the plane of the dial; but it will look most symmetrical in this last position. In whatever way it is fixed, the edge which projects the shadow must be in the plane of the meridian, and parallel to the earth's axis.

34. When the position of the plane of a dial in respect of the earth's axis is known, the determination of the hour lines is a geometrical problem by no means difficult. As at every hour the sun is in one or other of twelve great circles of the sphere, which intersect at the poles of the heavens, and which make equal angles with one another, the general problem to be resolved is evidently this: *Let there be twelve planes, which intersect in a straight line, and make equal angles with one another; and let these planes, indefinitely produced, meet another plane in any position whatever, to determine the lines in which they cut that plane.*

In resolving this problem, it will be convenient to begin with the more simple cases, and to reduce the others as much as possible to them.

Equinoctial Dial.

Equinoctial dial.

35. This dial, seen obliquely in its proper position, is represented by the upper part of Fig. 3. Its plane is parallel to the equator, and is the same as the plane of the equinoctial circle in the heavens; E is its centre, and EF its axis. As the hour circles in the heavens are perpendicular to the equinoctial circle, and divide it into 24 equal parts, the lines in which the plane of the dial cuts their planes, that is, the hour lines, will make 24 equal angles round the centre of the dial.

Plate CCXXVIII. Fig. 3.

It appears, then, that to delineate a dial of this kind, nothing more is necessary than to describe a circle on its plane, and to divide its circumference into 24 equal parts; and having drawn lines from the centre to the points of division, these will be the hour lines against which the characters denoting the hours are to be written; if the axis be now fixed perpendicular to the plane, the dial will be constructed.

In fixing this dial, the axis EF must be in the plane of the meridian, and must make with the horizontal meridian line, an angle equal to the latitude of the place, and then it will point to the pole of the heavens as it ought.

36. As the sun is one half of the year on the north side of the equinoctial, and the other half on the south side, it will be proper to trace hour lines on both faces of the dial; and in north latitudes the hours will be shewn on the upper face of the dial in summer, and on the lower face in winter; but on the equinoctial days, neither face will be illuminated.

The rays of the sun will always fall very obliquely on this dial in our latitudes, but to remedy this, a rim may be put round it, rising a little above the planes of its faces. The inside of the elevated part of the rim will be strongly illuminated by the sun's rays, and thus the hours will be more distinctly shewn.

37. A dial of this construction, which admits of being adjusted to any latitude, is delineated at Fig. 7. In this instrument, ABCD, and CDEF are two quadrangular pieces, (which may be of ivory, wood, or metal,) connected by means of a hinge at C, D. An equinoctial dial is described on each side of ABCD, or on one of them, and in the centre I, a style is placed at right angles to the planes of the dials. At G, in the middle of the piece EDCF, a magnetic needle is suspended, and covered with a plate of glass. At L, there is a quadrant fixed perpendicular to the plane of this piece, and divided into degrees. It passes through H, an aperture made to receive it in the upper piece. Fig. 7.

When the dial is to be used, it must be placed on a horizontal plane, so that the needle may be in the magnetic meridian. The upper piece must now be turned round the hinge, so that the planes of the two pieces may make with each other an angle equal to the latitude, as measured by the graduated quadrant. The hour of the day will then be shewn by the axis I, on one or other of the two, faces except on the day of the equinox.

Horizontal Dial.

38. A dial traced on a horizontal plane, is called a *Horizontal dial.* This is the most common and most useful of any, because it admits of being always illuminated when the sun shines. A dial of this kind is represented in perspective in Fig. 8. The point C is the centre, and CK, which is directed to the pole of the heavens, and makes with the plane of the dial an angle equal to the latitude of the place, is the axis. Horizontal dial. Plate CCXXVIII. Fig. 8.

To understand its nature and construction, let ABD be an equinoctial dial, whose axis EF is the prolongation of the axis of the horizontal dial; and let the planes of the two dials meet in the line PQ, and suppose the plane of the meridian to cut the plane of the

Theory and Construction.

horizontal dial in CM, and that of the equinoctial dial in EM; then the line PQ being the common intersection of the equinoctial and horizontal planes, which are perpendicular to the meridian, that line itself is perpendicular to the meridian. See GEOMETRY.

Let a plane passing through the sun's centre and the common axis of the dials, meet their planes in the lines EH, CH, these lines will manifestly be the positions of the shadows on the two dials at the same instant of time.

39. Now, at any given time, we know the angle HEM which the revolving shadow EH makes with the meridian line EM on the equinoctial dial, because it is the *horary angle* which the sun has to describe, or has described about the earth's axis, between the given time and noon, and which is always proportional to that time, reckoning 15 degrees of the angle to an hour. And in the triangle CEM, right angled at E, we know the angle ECM, which is always equal to the latitude of the place for which the dial is to be constructed; and from these we must find the angle HCM, which the hour line HC, on the horizontal dial, makes with CM, the meridian, or 12 o'clock line.

Let us denote the horary angle HEM, which the sun describes between the given time and noon, by the letter E, and the angle HCM, which the hour line on the horizontal dial makes with the meridian, by C, and let the angle ECM, the latitude of the place, be L; then, by plane trigonometry, in the two right angled triangles, EMH, CMH,

$$\text{HM} : \text{ME} :: \text{tan. E} : \text{rad.}$$

$$\text{and CH} : \text{HM} :: \text{rad.} : \text{tan. C};$$

therefore, *ex æquo inv.* (see GEOMETRY,)

$$\text{CM} : \text{ME} :: \text{tan. E} : \text{tan. C},$$

$$\text{but CM} : \text{ME} :: \text{rad.} : \text{sin. L};$$

$$\text{therefore, rad} : \text{sin.L} :: \text{tan. E} : \text{tan. C.}$$

Now, the first three terms of this proportion are known, therefore the last is also known; and we get this general formula for constructing a horizontal dial.

$$\text{tan. C} = \text{sin. L. tan. E.} \quad . \quad . \quad . \quad . \quad (1)$$

in which radius is supposed $=1$. The logarithmic formula, deduced from it, may be expressed in words at length, thus:

To the logarithmic tangent of the horary angle described by the sun between noon and the given time, add the log. sine of the latitude, and the sum, abating 10, *(the log. of rad.) is the logarithmic tangent of the angle which the hour line on the dial makes with the meridian line.*

40. EXAMPLE. Let it be required to calculate the angles which the hour lines on a horizontal dial, for Edinburgh, make with the meridian or 12 o'clock line: The latitude of Edinburgh being about 56°, a calculation for the hour lines of XI in the forenoon and I in the afternoon would be as follows:

log. tan. horary angle 15°	9.42805
log. sin. lat. 56°	9.91857
log. tan. 12° 32′	9.34662

Hence it appears, that the hour lines for XI in the forenoon, and I in the afternoon, must each make with the meridian an angle of 12° 32′.

The angles which the remaining hour lines make with the meridian may be found in the same way, and will be as follows:

Hour lines of X and II	25°	35′
IX and III	39	40
VIII and IV	55	8
VII and V	72	5
VI and VI	90	0

The hour lines of V in the morning, and VII in the evening, make the same angles with the meridian as the hour lines of VII in the morning and V in the afternoon; but they lie on opposite sides of the VI o'clock hour lines. In like manner, the hour lines of IV in the morning, and VIII in the evening, make the same angles with the meridian as the hour lines of VIII in the morning and IV in the afternoon, and so on.

Theory and Construction.

The construction of the dial is now very easy, as it requires nothing more than to make an angle of a given number of degrees. Thus, draw the meridian line CM (Fig. 9.) and cross it at right angles by the six o'clock hour line CG; and as the style of the dial must have some thickness, it will be proper to draw two parallel lines CM, C′M′ for the meridian line, so that the distance between them may be equal to that thickness.

PLATE CCXXVIII. Fig. 9.

From the points C, C′, draw the lines CI, C′XI on opposite sides of the meridian, so that the angles MCI, M′C′XI may be each 12° 32′; and these lines will be the hour lines of I in the afternoon, and XI in the forenoon; the former lying on the east and the latter on the west side of the meridian, when the dial is placed in its proper position. In the same way, all the other hour lines may be laid down on the plane of the dial, using a scale of chords, or a protractor, such as is commonly sold by mathematical instrument makers. Or a quadrant of a circle $p\,q$ may be described on C as a centre, and divided into 90 equal parts, and the hour lines drawn at once through the points of the arc indicating the number of degrees and minutes they ought to make with the meridian. The stile KCL (Fig. 8.) must be so constructed that the angle contained by CK and CL, the edges of one of its planes, may be 56°, the latitude of the place, and it may be fixed into the plane of the dial by two tenons at C and L let into openings made to receive them. The edge CK must stand directly over the meridian line CM, and then the afternoon hours will be shewn by the limit of the shadow of the triangular plane KCL.

The stile may have any shape, provided its edge CK be a straight line. It may even be a cylindrical rod, but in that case the hour lines ought to be tangents to its section with the plane of the dial. The angles they make with the meridian will, however, be the same.

41. Instead of an axis directed to the pole, we may substitute a vertical pin; for if, from any point K in the axis, a perpendicular KL be let fall on the meridian line, and the axis be removed, leaving the vertical line KL, it is evident that the shadow of its top K will come to any hour line at the same instant that the edge of the shadow of the axis CK would have fallen on that line.

To form this stile, we must, at any point L in the meridian, erect a vertical pin of such a height, that a line drawn from its top to the centre of the dial, may make with the meridian an angle equal to the latitude. In this case the meridian may be a single line if the stile have a sharp point, and then the extremity of the shadow will point out the hour of the day. This kind of stile, however, cannot indicate the hour for some time after sun-rise and before sun-set, because of the shadow extending beyond the limits of the dial.

The hours may also be indicated by the shadow of any point whatever, provided a line drawn from it to the centre of the dial pass through the pole of the world. Hence the stile may be any ornamental or emblematical figure: for example, Time and the hour may be shewn by the shadow of the point of his scythe, &c.

42. We shall here give a Table, calculated by the for-

mula of art. 39. by which a horizontal dial may be constructed for any place in Great Britain.

A Table of the Angles which the Hour-lines form with the Meridian on a Horizontal Dial for every half Degree of Latitude, from 50° to 59° 30′.

Latitude.	A. M. I. XI.	A. M. II. X.	A. M. III. IX.	A. M. IV. VIII.	A. M. V. VII.	A. M VI. VI.
50° ′	11°38′	23°51′	37°27′	53° 0′	70°43′	90° 0′
50 30	11 41	24 1	37 40	53 11	70 51	90 0
51	11 46	24 10	37 51	53 24	70 58	90 0
51 30	11 51	24 19	38 4	53 36	71 6	90 0
52	11 55	24 27	38 14	53 46	71 13	90 0
52 30	12 0	24 36	38 25	53 58	71 20	90 0
53	12 5	24 45	38 37	54 8	71 27	90 0
53 30	12 9	24 54	38 48	54 19	71 34	90 0
54	12 14	25 2	38 58	54 29	71 40	90 0
54 30	12 18	25 10	39 8	54 39	71 47	90 0
55	12 23	25 19	39 19	54 49	71 53	90 0
55 30	12 28	25 27	39 29	54 59	71 59	90 0
56	12 32	25 35	39 40	55 8	72 5	90 0
56 30	12 36	25 45	39 50	55 18	72 12	90 0
57	12 40	25 51	39 59	55 27	72 17	90 0
57 30	12 44	25 58	40 9	55 37	72 22	90 0
58	12 48	26 5	40 18	55 45	72 27	90 0
58 30	12 52	26 13	40 27	55 54	72 33	90 0
59	12 56	26 20	40 36	56 2	72 39	90 0
59 30	13 0	26 27	40 45	56 10	72 44	90 0

In this Table, the angles formed by the lines for V in the morning and VII in the evening, IV in the morning and VIII in the evening, &c. are not marked, because, it has been already observed, they are the same as those for VII in the morning and V in the evening, VIII in the morning and IV in the evening, only they lie on opposite sides of the VI o'clock hour lines.

Use of the Table.

The use of the Table may be easily comprehended: If the place for which a horizontal dial is to be made, corresponds with any latitude in the Table, the angles which the hour lines make with the meridian may be seen at once. For example, it appears that the hour lines of XI and I must, in the latitude of 56°, make angles of 12° 32′ with the meridian. If the latitude be not contained in the Table, proportional parts may be taken without any sensible error. Thus, if the latitude be 54°15′, and the angles made by the hour lines of XI or I be required; as it appears from the Table that the increase of 30′ in the latitude, viz. from 54° to 54° 30′, corresponds to an increase of 4′ in the hour angle at the centre of the dial, we may infer, that an increase of 15′ will require an increase of 2′ nearly; and therefore that the angle required will be 12° 16′.

Geometrical Construction of Horizontal Dials.

Geometrical construction of horizontal dials.

43. As every geometrical problem admits of various constructions, so the hour lines on a horizontal dial may be determined in various ways, according to the view that is taken of the subject. They may all, however, be deduced from the formula investigated in art. 39, namely, that radius is to the sine of the latitude, as the tangent of the horary angle described by the sun between any hour and noon, is to the tangent of the angle which the hour line on the dial makes with the meridian. From this formula we immediately derive,

Method I.

Plate CCXXVIII. Fig. 10.

44. Let CMO, C′M′O′ (Fig. 10.) be the meridian line on the dial, the space between CM, C′M′ being left for the thickness of the style, and CC′ its centre, and 6 C 6 the six o'clock hour line.

Fig. 11.

1. Make a right angled triangle *c m o*, Fig. 11. of any magnitude, having one of its acute angles *c* equal to the latitude of the place.
2. In the meridian, take CM and C′M′ equal to *c m*, the hypothenuse of the triangle, and MO and M′O′ equal to *m o*, the side opposite to the angle *c*.
3. Through M, M′ draw PQ perpendicular to CO.
4. On O and O′, as centres with OM as a radius, describe quadrants MH, M′H′.
5. Divide each quadrantal arc into six equal parts.
6. Through the points of division draw the lines O 1, O 2, O 3, &c. also O′ 11, O′ 10, O′ 9, &c. meeting PQ in *v*, *u*, *x*, &c. and in *r*, *s*, *t*, &c.
7. From the points C, C′ draw lines C 1 *v*, C 2 *u*, C 3 *x*, &c. to the points *v*, *u*, *x*, &c. and C′ 11 *r*, C 10 *s*, C 9 *t*, &c. to the points *r*, *s*, *t*, &c. and these will be the hour lines of the dial, viz. C 1 and C 11 will be the hour lines of I in the afternoon and XI in the forenoon, and C 2, C 10 the hour lines of II and X, and so on.
8. The hour lines before six in the morning, and after six in the evening, are to be found from the adjoining intermediate hours, as directed in art. 40.

The demonstration of this construction is obvious; for in the right angled triangles OM *v*, CM *v*, we have

CM : M *v* : : rad. : tan. MC *v*,

and M *v* : MO : : tan. MO *v* : rad.

Therefore, *ex æquo inv.* CM : MO : : tan. MO *v* : tan. MC *v*, but CM : MO : : *c m* : *m o* : : rad. : sin. lat.; hence, rad. : sin. lat. : : tan. MO *v* : tan. MC *v*.

Therefore, the angle MC *v* is rightly determined, (art, 39.) and the demonstration applies alike to all the hour lines.

This construction, although very simple, is rather inconvenient in practice, because the lines O4, O5, and O8, O7, may go off the surface on which the dial is to be delineated, before they meet the line PQ. The next construction has not this defect.

Method II.

Fig. 12.

45. Let CM, C′M′ be the double meridian line (Fig. 12.), and 6C6 the six o'clock hour line, and let *c m o* (Fig. 11.), be a right angled triangle, constructed as directed in the first operation of Method I.

1. On C, C′ the centres of the dial, with a radius equal to *c m*, the hypothenuse of the triangle *c o m* (Fig. 11.) describe semicircles on opposite sides of the meridian.
2. On the same centres, with a radius equal to *o m*, (the side opposite to the angle which is the latitude) describe other two semicircles also on opposite sides of the meridian.
3. Divide each quadrant of the two semicircles into six equal parts, at the points of division 1, 2, 3, &c. 11, 10, 9, &c. and let the numbers be written at the points of division, in the same order, in respect to the meridian, as the characters for the hours are to be placed on the dial.
4. Then, to find the position of any hour line, as, for example, that for three in the afternoon: Let D be the third point of division on the inner circle, and E the third point of division on the outer circle, reckon-

Theory and Construction.

ed from the meridian on the quadrant through which the afternoon hour lines are to pass. Draw EBA perpendicular to the meridian, and DB parallel to it, meeting the perpendicular in B.

5. Draw a straight line from C through B, and the line CB will be the hour line for III in the afternoon, as required.

And in the very same way may all the other hour lines be drawn on the dial.

To prove the truth of this construction, let EB meet the meridian in A, and join EC, which will evidently pass through D. Because BD is parallel to AC, CE : CD : : AE : AB ; but by construction, CE : CD : : rad. : sin. lat. ; and, by trigonometry, AE : AB : : tan. ACE : tan. ACB ; therefore, rad. : sin. lat. : : tan. ACE : tan. ACB ; now ACE is equal to the horary angle which the sun describes in three hours ; therefore CB is the hour line for three in the afternoon. (art. 39.)

Construction of Dialling Scales.

Construction of dialling scales.

46. There is another very elegant geometrical construction for the hour lines, by which scales may be made for the construction of dials, which save the labour of dividing circles.

Plate CCXXVIII. Fig. 13.

To construct these scales, divide AB a quadrant of a circle, into six equal parts. Draw the line *b a* to touch the middle of the arc at G. Draw lines from the centre through A and B, the extremities of the arc, to meet the tangent in *a* and *b*, and also through the divisions, to meet the tangent in the points against which the numerals VI, V, IV, &c. are placed. Then the line between the extreme points *a* and *b* is the *scale of hours*.

Next, divide EF, a quadrant of the same circle, into 90 equal parts, (only every tenth division is marked in the Figure). From the points of division draw perpendiculars to OF, the radius. Draw lines through E and the bottoms of the perpendiculars, and produce them, until they meet the circumference again in the points 10, 20, 30, &c. Transfer the chords of the arcs D 10, D 20, D 30, &c. (also the chords of the intermediate arcs not distinguished in the Figure) to a straight line *d f*, numbering them as in the Figure ; and the line *d f* will be the *scale of latitudes*.

If the chords of all the arcs from 0° to 90° of the quadrant EF be transferred to another straight line *e f*, a *scale of chords* will be formed, which is frequently wanted in making dials.

Construction of a Horizontal Dial by the Scales.

Construction of a horizontal dial by the scales. Fig. 14.

47. Let CM, C′M′ be the meridian, and 6 C′C′ 6 the six o'clock hour line. (Fig. 14.)

1. From the scale of latitudes take the extent from the beginning of the scale to the division corresponding to the latitude of the place for which the dial is to be made, and set it off from C to *a*, and from C′ to *a*′.

2. From the points *a*, *a*′, place lines *a b*, *a*′ *b*′, each equal to the whole length of the scale of hours, to terminate at *b* and *b*′ in CM, C′M′, the meridian line.

3. Transfer the divisions of the scale of hours to the lines *a b*, *a*′ *b*′, numbering them as in the Figure.

4. From the points C, C′ draw the lines C 1, C 2, C 3, &c. also C′ 11, C′ 10, C′ 9, &c. and these will be the hour lines of the dial.

The morning hours before VI, and evening hours after VI, are found as explained in the other constructions. And the stile is to be formed in all respects as described in art. 40.

Plate CCXXVIII. Fig. 13, 14.

To demonstrate the truth of this construction, let the latitude for which the dial is made be equal to the number of degrees in the arc E *p*, (Fig. 13.) Then, *p q* being drawn perpendicular to OF, and E *q* drawn meeting the circle in *r*, and D *r* joined ; it is manifest from the construction of Fig. 13. and Fig. 14. that the triangle D *r* E (Fig. 13.) is in all respects equal to the triangle *a* C *b* (Fig. 14.) so that D *r*=C *a*, *r*E=C*b*, and DE=*a b* ; and since in Fig. 13. rad. : sin. lat. : : EO : O *q* : : E *r* : *r* D ; therefore, in Fig. 14. rad. : sin. lat. : : *b* C : C *a*.

Let H (Fig. 14.) be the point in which any one of the hour lines (for example that for IV in the afternoon) meets *a b*. In the six o'clock line, place CN equal to C *b* ; join *b* N, and through H draw KHL parallel to CN, meeting the meridian in K, and the line *b* N in L ; and join CL. And because N *b* and *a b* are similarly divided at L and H, and *a* H and H *b* in Fig. 14. are respectively equal to *a* IV and IV *b* in Fig. 13 ; therefore N *b* in Fig. 14. and *a b* in Fig. 13. are similarly divided at L and IV. Now the triangles NC *b* (Fig. 14.) and *a* O *b* (Fig. 13.) are manifestly similar ; therefore it is easy to see that the angle *b* CL in Fig. 14. must be equal to *b* OIV in Fig. 13 ; and hence *b*CL in Fig. 14. must be equal to the horary angle described by the sun between noon and IV in the afternoon.

Now LK=*b* K : HK : : tan. LC *b* : tan. HC *b*. But *b* K : HK : : *b* C : C *a* : : rad. : sin. lat. ; therefore rad. : sin. lat. : : tan. *hor. ang.* : tan. HC *b*. Hence it follows, (art. 39.) that the angle which the hour line HC, or IVC, makes with the meridian, is of the proper magnitude : and the same may be proved in like manner of all the others.

Construction of Horizontal Dials by a Globe.

Construction of horizontal dials by a globe. Fig. 15.

48. The construction of a horizontal dial, and indeed of any dial whatever, as will appear farther on, may be very naturally deduced from the doctrine of the sphere. For, let *a* P B *p* (Fig. 15.) represent the earth, which we may suppose transparent, and let its equator be divided into 24 equal parts by meridian circles *a*, *b*, *c*, *d*, *e*, &c. one of which is the geographical meridian of any given place, as Edinburgh, which we may suppose at the point *a*. If now the hour of 12 were marked at the equator, both upon that meridian and the opposite one, and all the rest of the hours in order on the other meridians, they will be the hour circles of Edinburgh, and the sun will move from one of them to another in an hour.

Now, if the sphere had an opaque axis, terminating at the points P *p*, the shadow of the axis, which is in the same plane with the sun and each meridian successively, would fall upon every particular meridian, and hour, when the sun came to the opposite meridian, and would therefore shew the time at Edinburgh, and all other places on the same meridian. If the sphere were now cut through the middle, by a plane ABCD, in the rational horizon of Edinburgh, one half of the axis would be above the plane, and the other half below it ; and if straight lines were drawn from the centre of the plane to those points where its circumference is cut by the hour circles of the sphere, those lines would be the hour circles of an horizontal dial for Edinburgh ; for the shadow of the axis would fall upon each hour line

Theory and Construction.

of the dial when it fell on the like hour circle of the sphere.

49. It appears, then, that to construct a horizontal dial by the terrestrial globe, we must place the globe in such a position, that the arc of the brazen meridian between the pole and horizon may be equal to the latitude of the place, and that any one of the meridians on the globe may coincide with the brazen meridian; and then the arcs of the horizon between its north point and its intersections with the 24 meridians on the globe will be the measures of the angles which the hour lines on the dial must make with the meridian line.

50. From the same principles we may derive immediately the formula which was investigated at art. 39. For, let PHp be any hour circle which cuts the horizon in H, then in the right angled spherical triangle PBH, there are given PB, one of its sides adjacent to the right angle B, equal to the latitude, and the angle HPB at the pole, which is equal to the hour angle from noon, to find HB, the arc of the horizon between the meridian and hour circle, passing through the sun, which arc is the measure of the angle at the centre of the dial contained by the meridian and hour line corresponding to that hour circle.

By the principles of spherics, (see Spherical Trigonometry), in any right angled spherical triangle, radius is to the sine of either of the sides about the right angle, as the tangent of the adjacent angle to the tangent of the other side about the right angle; that is, in the present case, as radius to the sine of PB, the latitude; so is the tangent of HPB, the horary angle in the heavens, to the tangent of HEB, the angle made by the hour line and the meridian at the centre of the dial.

Vertical South or North Dials.

Vertical south or north dials. Plate CCXXVIII. Fig. 16, 17.

51. These dials are described upon vertical planes, facing directly to the south and north. They are represented in Fig. 16. and Fig. 17.

As the planes of these dials coincide with the *prime vertical*, that is, the great circle of the sphere which passes through the zenith and the east and west points of the horizon, their intersections with the meridian or the XII o'clock hour line, will be a vertical line. The theory of these dials might be investigated exactly in the same way as that of the horizontal dial, and particular rules formed for their construction; but this is not necessary; for the geometrical constructions which have been investigated for a horizontal dial, may be made to apply to all dials whatever, by considering, *that if a horizontal dial were transferred from the place for which it was made, to any other place on the earth's surface, and fixed there in a position parallel to its original position, that is, with its plane parallel to the horizon of the place for which it was made, and its axis, as before, pointing to the pole of the heavens; then, in its new position, it will indicate the hour of the day at its original position, precisely as it did before it was removed.* This proposition, although not exactly, is almost exactly true, because of the great distance of the sun from the earth in comparison to the distance of one place on the earth from another.

52. From the above principle we may infer, that any plane dial whatever, at a given place, will be a horizontal dial for some place or other of the earth; and, therefore, to construct a dial on a given plane, we have only to find what place of the earth has its horizon parallel to that plane, and then on the given plane to construct a horizontal dial for that place, and it will shew the hour of the day there. This, however, may not be the hour of the day at the place where the dial is intended to shew time, but then it will differ from the true hour there always by the same given quantity, namely, by the difference of the longitudes of the two places reckoned in hours and minutes of time. For example, if it should be found that a certain plane at London was parallel to the horizon of St Petersburg; then a horizontal dial constructed on the plane for the latter place, would show the hour at St Petersburg. But as the difference of longitude between London and St Petersburg is about 30 degrees, corresponding to two hours in time, the dial would indicate noon when it was only ten in the morning at London; and it would shew one o'clock when the true time at London was eleven, and so on. However, the dial would be adapted to London if we wrote the character for the hour ten on the St Petersburg meridian line, and that for eleven on the one o'clock hour line, and so with the other hours.

53. The zenith of any place being in a line passing through the plane perpendicular to its horizon, it is easy to see that two places on the earth's surface which have their horizons perpendicular to one another, must have their zeniths 90 degrees asunder. Hence it follows, that a vertical south or north dial at any place, would be a horizontal dial to a place 90° south or north from that place, and on the same meridian. A vertical south or north dial at Edinburgh, for instance, the latitude of which is 56°, would be a horizontal dial at a place on the same meridian, and in 34° of south latitude, and it would shew the same hour of the day at both places, because the time of noon happens at both at the same instant.

54. Hence, if we put E for the horary angle from noon, and C for the angle which the corresponding hour line makes with the meridian of a north or south dial, and L for the latitude of the place, we get immediately, from the formula of art. 39,

$$\text{Tan. } C = \text{Cos. } L \text{ tan. } E \quad \ldots\ldots\ldots \quad (2)$$

a general formula for constructing a north or south dial; and by this, the angles which the hour lines make with the meridian may be computed. The other three methods of constructing a horizontal dial, (art. 44—48), apply equally to vertical south or north dials, only substituting the complement of the latitude, or what it wants of 90° for the latitude, observing that the axis must make with the plane of the dial an angle equal to the complement of the latitude, and must be in the meridian, and then it will point to the pole of the world, as must be the case in all dials.

55. In north latitudes, a north dial is only illuminated when the sun is on the north side of the equator; and the nearest times of the day to noon that can be shewn by it, are those at which the sun passes the prime vertical on the day of the summer solstice. A south dial can never be illuminated before six in the morning, nor after six in the evening; because, when the sun rises earlier, and sets later, he does not pass the prime vertical so early as six in the morning, and he crosses it again before six in the evening. It will be unnecessary, therefore, to describe upon either more hour lines than can be wanted.

Vertical East and West Dials.

56. These dials are traced upon vertical planes, fa-

Theory and Construction.

cing directly east and west; their planes, therefore, coincide with the plane of the meridian, and pass through the poles of the world.

Vertical east and west dials. Plate CCXXVIII. Fig. 18.

To explain the nature of these dials, let us suppose that NS, Fig. 18. is a straight line traced upon their planes in the direction of the earth's axis, and that it is crossed at right angles by a straight line EQ, which will be the intersection of the planes of the equinoctial and the meridian. Let us also suppose, that AB is a thin cylindrical rod, held directly over the line $a\,b$, and parallel to it, by two supports A a, B b; and that this rod passes through C the centre of a circle, which lies in the plane of the equinoctial circle, and which touches the plane of the meridian in c, the bottom of a perpendicular C c: this circle will evidently be an equinoctial dial, of which AB is the axis.

Let CK be the shadow which the axis projects on the plane of the circle, and let it be produced to meet the vertical plane in k; then a line drawn through k, perpendicular to EQ, will evidently be the direction of the shadow which the rod AB projects on the vertical plane, at the same instant of time that it projects on the equinoctial dial the shadow CK; and as the hours are indicated on the equinoctial dial by the position of the revolving shadow CK, they will also be shewn on the vertical plane EQNS, by the successive positions of the rectilineal shadow F k F, which will always be parallel to NS.

Now, as the plane a AB b is perpendicular to the plane of the meridian, and passes through the poles, it must be the plane of the six o'clock hour circle, or that circle in the heavens, passing through the poles of the world, in which the sun is always seen at six in the morning and six in the evening. Therefore the arc c K of the equinoctial dial, intercepted between the perpendicular C c and C k, the position of the shadow at any time will be the measure of the horary angle described by the sun in the heavens, between six o'clock and that time; and the straight line $c\,k$, the distance of the shadow of the rod AB from the line $a\,b$ immediately under it, will be the tangent of that arc to the radius C c.

57. Let the horary angle from six o'clock be denoted by E′, and let ck, the distance of the hour line from $a\,b$, be x; also let C c, the height of the rod above the plane of the dial, be denoted by d, then because rad. : tan. E′ :: d : x, the general formula expressing the position of the hour lines on an east or west dial, in respect of the line $a\,b$, will be (supposing radius$=$1)

$$x=d \text{ tan. } E' \quad . \quad . \quad . \quad . \quad . \quad (3)$$

from which it appears, that, in these dials, the position of the hour lines in respect of each other is altogether independent of the latitude of the place. Indeed the same thing might have been inferred from what has been said in art. 51. and 52, for a vertical east or west dial for any place whatever would manifestly be an horizontal dial at the equator.

Geometrical construction of Vertical East and West Dials.

Geometrical construction of vertical east and west dials. Plate CCXXIX. Fig. 1, 2.

58. The geometrical construction of these dials will be as follows:

1. On the east or west vertical plane, draw the horizontal line HR, (Figs. 1. and 2.) and assume in it any point c for the bottom of the style, the upper extremity of which is to project a shadow on the hour lines.

2. Through the point c draw the line NS, so as to make with HR an angle N c R, equal to the latitude of the place. The angle NcR must be towards the right hand on an east dial, but towards the left in a west dial, and the line NS will point to the poles of the heavens.

3. Through c draw EcQ perpendicular to NS, and EcQ will be the equinoctial.

4. In c S take $c\,b$ equal to the intended height of the stile, and on b for a centre, with $b\,c$ as a radius, describe a semicircle.

5. Divide the semicircle into 12 equal parts.

6. From b draw lines through the points of division to meet the line EQ.

7. Through the points of intersection draw lines perpendicular to EQ, and these will be the hour lines on the dial against which the hours are to be written, as in the Figure.

8. At the points a, b, the style is to be erected (see Fig. 3.) so that its height A a may be equal to $b\,c$, which is also the distance between the hour lines of 6 and 9, and the dial is finished. Plate CCXXIX. Fig. 3.

The east dial will shew the morning hours until it be nearly noon, and the west dial will shew the afternoon hours; but neither can indicate the time of noon otherwise than by the sun being in the plane of the dial.

The truth of the construction follows too obviously from the formula, (art. 54.) to require any formal demonstration.

Polar Dial.

59. A polar dial is that which is traced on a plane perpendicular to the meridian, and passing through the poles; therefore, like east and west dials, the axis of the sphere lies in its plane; and to shew the hours, its stile must be formed like theirs, and fixed over the meridian line. Polar dial.

The construction of this dial, which is represented at Fig. 4. will differ in no respect from that for an east or west dial, except that in these, the line NS, which passes through the pole, makes with the horizontal line HR an angle equal to the latitude; but in the polar dial, the lines NS and HR are perpendicular to one another: for if an east or west dial were to be turned about the six o'clock hour line as an axis, so that the plane of the dial were perpendicular to its former position, it would then become a polar dial, and what was before the hour line for six would be in its new position the hour line for noon. Fig. 4.

This kind of dial may shew time from a little after six in the morning to a little before six in the evening, provided it be of sufficient extent to admit of the shadow meeting its plane. At the hours of six in the morning or evening, its plane passes through the sun, and therefore is not illuminated.

If E denote the horary angle from noon, and x and d represent the same things as in the formula for east and west dials, the formula for constructing the polar dial will be,

$$x=d \text{ tan } E. \quad . \quad . \quad . \quad . \quad (4)$$

Vertical Declining Dials.

60. Any dial described on a vertical plane that does not directly face one of the cardinal points, is called a *vertical declining dial;* and of these there may be four Vertical declining dials.

Theory and Construction.

Vertical declining dials.

kinds, viz. south-east, south-west, north-east, and north-west decliners.

The *declination* of any plane, whether vertical or inclined, is an arch of the horizon intercepted between the plane and the prime vertical; or it is the arch of the horizon intercepted between the meridian and a vertical plane, which is also perpendicular to the proposed plane.

The *meridian* of any dial plane is a plane that passes along the axis, or edge of the stile, and is perpendicular to the plane of the dial.

The *substile* of a dial is the common section of its plane, and the plane of its meridian. In horizontal, and in vertical south and north dials, the substile coincides with the twelve o'clock hour line; but in declining dials this is not the case.

The *difference of longitude* of a dial plane is the angle which the plane of its meridian makes with the meridian of the place.

Plate CCXXIX. Fig. 5.

61. Let PQ, Fig. 5, be a vertical plane, a wall for example, having any aspect; and let us suppose that upon its face that looks towards the south, an axis or stile OC, has been fixed at O, in a position parallel to the axis of the diurnal motion, by what has been taught in art. 32. and 33.

It appears, in the first place, that the vertical line OB drawn from the point in which the stile meets the wall, will be the 12 o'clock hour line; for it is common to all the vertical planes which pass through C, and consequently must be the intersection of the plane of the dial, and the meridian of the place.

From C, the extremity of the stile, draw CB perpendicular to C XII, thus forming the right angled triangle OBC, which will be entirely in the plane of the meridian; and therefore the prime vertical WOE is perpendicular to it. Let us suppose that at any hour, for example two in the afternoon, the horary plane, (or plane passing through the axis and the sun,) cuts the prime vertical WOE in the direction Oy, and the plane of the dial POQ in the direction OY; the first of these lines indicates the hour on the prime vertical; and the second shews it on the plane of the dial; but to trace the line OY, we must know the angle BOY, and the whole difficulty of constructing the dial lies in the determination of this angle.

62. Let us suppose a horizontal plane to pass along CB, and meet the horary plane COy in the line CYy; then it is manifest that BCY may be considered as the plane of a horizontal dial, of which C is the centre, CO the axis, CB the meridian line, and CY the hour line for two in the afternoon; therefore the angle BCY will be known by formula 1. (art. 39.) And because the horizontal lines BC, By, lie, the one in the meridian, and the other in the prime vertical, they contain a right angle; now the angle YBy is the declination of the plane, (art. 60.) therefore CBY is its complement, and is known, because we suppose the declination known; hence all the angles of the triangle BCY are known.

Let the latitude of the place for which the dial is to be constructed be expressed by L, and the angle yBY, or EOQ the declination of the plane by D; and, as in the formula of art. 39, let the angle C, made by the hour line of a horizontal dial for the latitude L and the meridian line BC be denoted by C, then, in the triangle BCY, we have the angle at C=C, the angle B=90°—D, and therefore the angle BYC=180—(90—D)—C=90—(C—D.)

In the right angled triangles, OBC, OBY, which have OB, one of the sides about the right angles, common to both, we have, by the principles of trigonometry,

BC : BY : : tan. BOC, or co-tan. OCB : tan. BOY.

But in the triangle BCY, we have also

BC : BY (: : sin. Y : sin. C) : : cos. (C—D) : sin. C.

Therefore,

Cos. (C—D) : sin. C : : co-tan. OCB : : tan. BOY.

Now, the three first terms of this proportion are given, because the angles C and D are given, and also the angle OCB, which is the latitude; therefore, the fourth term, or the tangent BOY is known, and hence the angle BOY itself is known.

63. From the foregoing investigation, and the formula of art. 39, we derive a formula for the construction of a vertical declining dial, which may be expressed thus:

Let L=the latitude of the place.

D=the declination of the dial, reckoned from the east towards the south.

E=the horary angle the sun has described since noon.

O=the angle BOY, which the shadow has described about the centre of the dial since noon.

C=the angle which the shadow has described about the centre of a horizontal dial for that place in the same time, and which is found by the formula,

Tan. C=sin. L tan. E. (art. 39.)

then we have

Cos. (C—D) : sin. C : : cot. L : tan. O.

and hence,

$$\text{Tan. O} = \frac{\text{cot. L sin. C}}{\text{cos. (C—D)}} \quad \ldots \quad (5.)$$

In the construction from which the preceding formula was derived, we considered the half of the plane of the dial, which passed between the meridian and the prime, vertical, and hence we found the angle CBY=90°—D; however, the formula is general for all horary angles, only, in conformity to the law of geometrical continuity, if we regard the values of C for the afternoon as positive, those for the forenoon must be considered as negative; and as, by the Arithmetic of Sines, we have —sin. (+C)=sin.(—C), and cos. (—C—D)=cos.(C+D), the formula for the forenoon hours is,

$$\text{Tan. O} = -\frac{\text{cot. L sin. C.}}{\text{cos. (C+D)}}$$

The negative sign shews that the angle O ought to be taken on the other side of the meridian.

64. The above formula, although very simple, and well adapted to calculation, has yet the inconvenience of requiring two operations for each hour line; viz. one to find C from E, the horary angle, and another to find O from C. It will, therefore, be proper to investigate a formula that shall give the value of O in terms of E at once.

For this purpose, in the denominator of the formula, instead of cos. (C—D), put its equal cos. C cos. D+sin. C sin. D, (Arithmetic of Sines, art. 7.) and after dividing the numerator and denominator by cos. C, let tan. C be put for $\frac{\text{sin. C}}{\text{cos. C}}$, and the result will be,

$$\text{Tan. O} = \frac{\text{co-tan. L. tan. C}}{\text{cos D+sin. D tan. C}}$$

Now, let sin. L tan. E be substituted for tan. C, (art. 39.) and again, $\frac{\text{sin. E}}{\text{cos. E}}$ for tan. E, and then after reducing, we find, Vertical declining dials.

$$\text{Tan. O} = \frac{\text{cot. L sin. L sin. E}}{\text{cos. E cos. D} + \text{sin. L sin. E sin. D}}$$

Let d be such an arc, that

$$\text{Tan. } d = \text{sin. L tan. D},$$

from which it follows, that $\text{cos. D} = \frac{\text{sin. L sin. D cos. } d}{\text{sin. } d}$.

This value of cos. D being substituted in the formula, it becomes

$$\text{Tan. O} = \frac{\text{cot. L. sin. } d}{\text{sin. D}} \times \frac{\text{sin. E}}{\text{cos. E cos. } d + \text{sin. E sin. } d}.$$

Now, the denominator of the fraction is evidently cos. (E—d), or cos. (d—E). Hence, we have the following very simple formula for the calculation of the angle which the shadow of the axis of a vertical declining dial describes in any time before or after noon.

Let L be the latitude of the place,
D the declination of the dial,
E the horary angle described by the sun, reckoning from noon,
O the angle described by the shadow.

Find an angle d, such that $\text{tan. } d = \frac{\text{sin. L tan. D}}{\text{rad.}}$;

Also a line which we shall call the tangent of an angle a, such that $\text{tan. } a = \frac{\text{co-tan. L sin. } d}{\text{sin. D.}}$

$$\text{Then, tan. O} = \frac{\text{tan. } a \text{ sin. E}}{\text{cos. (E}-d)} \quad \ldots . \ (6)$$

for the afternoon hours,

and $\text{tan. O} = \frac{\text{tan. } a \text{ sin. E}}{\text{cos. (E} + d)}$ for the forenoon hours.

In applying the formula, if the horary arch E be less than the angle d, we may take d—E instead of E —d, for cos. (E—d) and cos. (d—E) are expressed by the same quantity.

65. We shall now give examples of the application of the formula.

Vertical south dial declining westward.

EXAMPLE 1. Let it be required to find the angles which the hour lines make with the meridian in a vertical south dial, that declines to the west 36°, the latitude of the place being $54\frac{1}{2}$ degrees.

In this example, the dial has the same aspect as that from which the formula has been investigated; for the half of the plane on which the afternoon hours are drawn passes between the meridian and prime vertical, making with it an angle equal to 36°; hence we have,
L=54° 30′; D=36°.

Calculation of the angle d;

	Logarithms.
Tan. D	9.86126
Sin. L	9.91069
Tan. (d=30°36′)	9.77195

Calculation of the quantity, tan. a.

Co-tan. L	9.85327
Sin. d	9.70675
Sin. D Ar. Comp.	0.23078
Tan. a	9.79080

As it is only the logarithm of the quantity tan. a that we want, we have no occasion to seek for the angle itself.

Next, to find the angle made by an hour line, as, for example, I in the afternoon, we have E=15°, and d—E=15° 36′, and the calculation may stand thus,

	Logarithms.
Sin. E	9.41300
Tan. a	9.79080
Cos. (d—E) Ar. Comp.	0.01630
Tan. (O=9° 26′) . . .	9.22010

Hence it appears, that the hour line of I in the afternoon makes an angle with the meridian of 9° 26′.

For XI in the forenoon we have E=15°, and d+E =45° 36′.

Sin. E	9.41300
Tan. a	979080
Cos. (E+d) Ar. Comp.	0.15511
Tan. (O=12° 52′)	9.35891

The angles made by the remaining hour lines, may be found in the same manner; and these, as well as the *data* from which they are derived, are expressed in the following Table, which extends from IX in the morning to VIII in the evening, the time during which the dial is illuminated.

Given L=54° 30′, D=36 0; hence d=30° 36′, log. tan. a=9.79080.

Hours.	E.	E±d.	Angle O.
IX A. M.	45°	75° 36′	60° 21′
X	30	60 36	32 10
XI	15	45 36	12 52
XII	0	30 36	0 0
I P. M.	15	15 36	9 26
II	30	0 36	17 10
III	45	14 24	24 17
IV	60	29 24	31 34
V	75	44 24	39 52
VI	90	59 24	50 30
VII	105	74 24	65 44
VIII	120	89 24	88 52

This dial is represented in Fig. 6. And it is evident that if the hour lines be produced, and the axis continued on the other side of the plane, (considered as transparent,) we shall have a north dial declining to the east 36°.

PLATE CCXXIX. Fig. 6.

Vertical south dial declining eastward.

EXAMPLE 2. Suppose a vertical south dial to decline east 49°, in the latitude $51\frac{1}{2}$ degrees.

In this case, the plane of the dial passes between the north and east points; therefore, if we reckon the declination from the east towards the south, in the present case, D=360°—49°. Let D′=49°, then D=360 —D′; hence tan. D=—tan. D′; and since the sign of tan. d depends on that of tan. D, it follows that tan. d is negative, and d between 270° and 360°. Let d'=360 —d; then tan. d'=(— tan. d=—sin. L tan. D)=sin. L tan. D′, and cos. (d—E)=cos. $\{360° - (d' + \text{E})\}$ =cos.(d'+E); also cos.(d+E)=cos. $\{360 - (d' - \text{E})\}$ = cos. (d'—E). Hence, in this case, our formula, (art. 64.) becomes

$$\text{tan. O} = \frac{\text{tan. } a \text{ sin. E}}{\text{sin. } (d' + \text{E})} \text{ for the afternoon,}$$

$$\text{and tan. O} = \frac{\text{tan. } a \text{ sin. E}}{\text{sin. } (d' - \text{E})} \text{ for the forenoon.}$$

Vertical declining dials.

To find d'

Tan. D'	10.06084
Sin. L	9.89354
Tan. (d'=42°)	9.95438

To find tan. a,

Cot. L	9.90061
Sin. d'	9.82551
Sin. D' Ar. Comp.	0.12222
Tan. a	9.84834

From the angle d a series of angles $d+15°$, $d+30°$, &c. is to be formed for the afternoon hours, and another $d—15$, $d—30$, &c. for the forenoon hours, and from these the hour angles at the centre of the dial may be calculated exactly, as in the last example. The *data* and the results obtained are given in the following Table:

Given L=51° 30′, D′=49 0	hence d'=42°, log. tan. a=9.84834.		
Hours.	E.	$E \pm d'$.	Angle Ô.

I P.M.	15	57	18 32
II	30	72	48 47

PLATE CCXXIX. Fig. 7.

This dial is represented in Fig.7. If the hour lines were produced, and the axis continued through the plane, we would evidently have a north dial declining westward.

In general, to make a north declining dial, we have only to make a south declining dial, whose declination is the same, and lies the same way, and then turn it upside down, and it will be a north declining dial; but the hours must be numbered the contrary way; so that the two examples we have given will apply to all the varieties of declining dials.

66. The formula which has been investigated in article 64, gives the position of the hour lines immediately, when the latitude of the place and declination of the plane are known. But there is another method of constructing a declining dial, by considering it as a horizontal dial for some place of the earth, as explained in art. 52. and finding the latitude of that place, and the difference between its longitude and that of the place where the dial is to shew the hours. The first of these is equal to the angle which the axis of the dial makes with its plane, that is, the angle which the axis makes with the substile; and the second is the time which the shadow takes to pass from the XII o'clock hour line to the substile, from which the angles contained by these lines may be found. These three elements being known, viz. the latitude and longitude of the place where the dial would be horizontal, and the angle made by the twelve o'clock hour line and substile, the construction of the dial is reduced to that of a horizontal dial.

67. The elements for constructing the dial in this way, may be found by spherical trigonometry, as follows:

PLATE CCXXIX. Fig. 8.

Let SN z be the meridian, in which Z and z are the zenith and nadir, and P, p the poles. Let SEN be the horizon, S and N being the south and north points, and E the east. Let ZF z be any vertical plane, or great circle, on which the dial is to be drawn; let this plane meet the horizon in F, and the meridian in the vertical line ZO z, and let it be cut perpendicularly in A a by the plane of a great circle PA p passing through the poles. Then, from the construction of the figure, it appears that O p or OP is the axis of the dial, (according as it faces towards the south or north), O z or OZ the twelve o'clock hour line; and O a or OA the substile, (Art. 58.)

In the right angled spherical triangle ZAP, (of which A is the right angle) PZ is the latitude of the place where the dial is to indicate time; the angle AZP, which is measured by the arch of the horizon FN, is the complement of EF, the declination of the plane; and these are both given to find AP the measure of the angle contained by the axis OP and substile OA, also AZ the measure of the angle which the substile makes with the vertical or twelve o'clock hour line; and, lastly, the angle ZPA, which is the difference of longitude of the plane, (Art. 60.)

By the principles of spherics, (see TRIGONOMETRY, *Spherical*), in the triangle ZAP,

Rad.: sin. ZP : : sin. Z : sin. AP
Rad.: cos. Z : : tan. ZP : tan. AZ
Rad.: cos. ZP : : tan. Z : cot. P.

Hence, putting L for the latitude of the place where the dial is to be constructed, and D for the declination of the dial, we get

Rad.: cos. L . : cos. D : sin. lat. of dial,
Rad.: sin. D : : cot. L : tan. of angle made by Sub.&Ver.
Rad.: sin. L : : cot. D : cot. dif. of long. of dial.

Thus, it appears, that the dial would be horizontal at a place of which the sine of the latitude is cos. L cos. D, and the cotangent of its difference of longitude equal to sin. L cot. D; and, moreover, that the tangent of the angle contained by the meridian line traced on the dial for that place, and the vertical or twelve o'clock hour line, where it is to be fixed, is equal to Sin. D cot. L; and from these three *data* the dial may be constructed, either arithmetically or geometrically, by the formula of art. 39, or the rules of art. 43—47, for a horizontal dial. And the hour lines must be so calculated, that one of them, to be taken as the twelve o'clock hour line, may coincide with the vertical line. To do this, we must form a series of arcs, by the repeated addition of 15° to the difference of longitude, on the one hand, and by the repeated subtraction of 15° on the other, until at last there be a remainder less than 15°. Then we must take the difference of longitude and these arcs as the successive values of E in the formula of art. 39, and the corresponding values of C will be the angles which the hour lines on one side of the substile make with it, and the angle corresponding to the difference of longitude, will evidently be equal to the angle the vertical line makes with the substile. Again, by adding repeatedly 15 degrees to the difference between 15°, and the remainder left in forming the first series; this difference and the succeeding terms of the series being put

Theory and Construction.

for E, will give the angles the hour lines make with the substile on the other side. The reason of this is too evident to require particular explanation.

The ingenious diallist may verify the calculations of the angles in the two examples of our first method by this second method; and he will find, that in the first example, the angle made by the axis and substile is 28° 1′, the angle made by the substile and vertical is 22° 45′, and the difference of longitude 41° 45′.

In the second example, the axis makes with the substile an angle of 24° 6′, the substile with the vertical an angle of 30° 59′, and the difference of longitude is 55° 47′.

The dial of Ex. 1. would therefore be a horizontal one for the lat. 28° 1′, and that of Ex. 2. for the lat. 24° 6′.

To find the Declination of a Plane.

To find the declination of a plane.

Plate CCXXIX. Fig. 9.

68. We shall suppose that CO, the axis of the dial, (Fig. 9.) has been fixed, according to the method explained in art. 32. and that the meridian line O XII has been traced, as the foundation of all the other operations. From C, the extremity of the axis, let fall a perpendicular CB on the meridian line; and mark the point B where it meets the line; then through B trace a horizontal line *h* BH on the plane of the dial, and mark several points on it, such as H, *h*, equally distant from the point B. This done, measure very accurately all the sides of the triangles CBH, CB *h*; and in each calculate the angle at B. These angles ought to be the supplements of one another, and hence we may prove the accuracy of the observation. If they are both right angles, the plane is perpendicular to the meridian, and has no declination; but if they are unequal, the difference between each and a right angle is the declination of the plane.

The declination may also be easily found by placing a mark at a great distance in the plane of the dial, and then determining the position of this mark in respect of the meridian line traced on the horizontal plane; an operation which may be performed by any instrument for measuring angles. Or otherwise, the eye may be placed in the direction of the plane, so as to observe the instant when some one of the heavenly bodies passes the plane, and the hour of this observation being noted, the azimuth of the plane may be easily calculated.

Inclining Dials.

Inclining dials.

69. Inclining or oblique dials are traced on planes which stand at oblique angles to the horizon. They are either *reclining* or *proclining*. A reclining plane is one that leans backwards from an observer, and a proclining plane, which is also sometimes called an *inclining* plane, leans forwards.

The reclination and proclination of a plane is the angle it makes with a vertical plane, or it is the number of degrees that the plane leans from or to an observer, reckoned from the zenith. But *inclination* is properly the angle a plane makes with the horizon.

Fig. 10.

70. Whatever be the situation of a plane on which a dial is to be made, it is always possible to trace upon it a meridian line OB, in the direction of two plumb-lines, as explained in art. 32; and to fix at O, a point in that line, (Fig. 10.) an axis OC, pointing to the pole of the world. From C, the extremity of the axis, let a perpendicular BC be drawn to the meridian line, meeting it in B, and forming the right angled triangle COB. As the lines CB, BO, may be measured, the angle COB may be found.

Plate CCXXIX. Fig. 10.

Now, if we suppose the plane to be a vertical dial at some place of the earth, then OB will be a vertical line at that place, and the angle COB the complement of its latitude, which will therefore be known. If, in addition to this, we knew the declination of the plane, we might calculate the angles which the hour lines make with the meridian line, by the formula of art. 62. But it is easy to find the declination; for the horizon ought to be perpendicular to the vertical line OB. Now BC is also perpendicular to OB; therefore, if in *h*BH, a perpendicular to OB, we take BH=B*h*, and join CH, C*h*, the triangles CBH, CB*h*, will lie in the hypothetical horizon, and the inclination of the plane to the hypothetical meridian OBC may be determined, as shewn in art. 66.

71. If, besides the position of the meridian and the axis, we know the declination and reclination of a plane, then we may find the latitude of a place, where the plane would be a vertical declining dial, and also the declination of the dial at that place, and with these data find the angles which the hour lines make with the meridian by the formula for vertical dials, given in art. 62. Or else we may find the latitude and longitude of a place, where the plane would be a horizontal dial, and thence find the position of the substile, and construct the dial by the rules for a horizontal dial.

Fig. 11.

72. To begin with the first of these methods. Let SHN*h* be the meridian; (Fig. 11.) P*p* the axis of the sphere; Z the zenith of the place where a dial is to be made; SEN the horizon; S, E and N, the south, east and north points respectively. Also, let *h*FH be a plane or circle of the sphere on which the dial is to be made, and which meets the horizon in F, and intersects the plane of the meridian in the line H*h*; then PO*p* will be the axis of the dial, and HO*h* the meridian line. Moreover, the arch EF between the east point of the horizon and the plane will be its *declination*; and the spherical angle HFN its *inclination* to the horizon, or the complement of its *reclination* from the vertical position.

Let *s*E*n* be the horizon of the place which has H for its zenith, (and of course where the plane HF*h* would be a vertical declining dial,) and let it cut the plane in *f*. Because the two horizons SEN, *s*E*n* are perpendicular to the meridian, their intersection E will be the east point in both.

Let L=PN, the given latitude of the place where the dial is to be made.

D=FE, the given declination of the dial.

R=Comp. of angle *f*FE, its given reclination.

λ=P*n*, the latitude of the place where the dial would be vertical, which is to be found.

Δ=E*f*, its declination there, which is also to be found.

Then λ—L=N*n*=measure of angle FE*f*.

In the spherical triangle E*f*F, right angled at *f*, we have, by spherics,

Rad. : sin. EF :: sin. F : sin. E*f*,
Rad. : cos. EF :: tan. F : cot. E.

From these proportions, we get

$$\left.\begin{aligned}\text{Sin.}\,\Delta &= \frac{\text{cos. R sin. D}}{\text{rad.}}\\ \text{Cot.}(\lambda-\text{L}) &= \frac{\text{cot. R cos. D}}{\text{rad.}}\end{aligned}\right\}\ldots\ (7)$$

From these equations, we get the arcs λ and Δ, which

Theory and Construction.

being substituted instead of L and D in the formula art. 64, it will be a general expression for the angle O, which the shadow makes with the meridian line on the reclining dial.

Plate CCXXIX. Fig. 11.

73. Example.—Let it be required to find the hour lines on a south dial plane FHh, (Fig. 11.) that declines westward 25°, and reclines 15° in latitude $54\frac{1}{2}$.

In this example, D=25°, R=15°, L=54° 30′.

To find Δ.		To find λ.	
Rad. . . .	10.00000	Rad.	10.00000
Cos. R . . .	9.98494	Cot. R . . .	10.57195
Sin. D . . .	9.62595	Cos. D. . . .	9.95728
Sin.(Δ=29° 6′)	9.61089	Cot.(λ—L)=16° 27′	10.52923

Hence λ=(λ—L)+L=16° 27′+54° 30′=70° 57′.

As the dial declines to the west, we have (art. 64.)

$$\text{Tan. O}=\frac{\tan.\,a\ \sin.\,\text{E}}{\cos.\,(\text{E}-d)}\ \text{for the afternoon.}$$

$$\text{Tan. O}=\frac{\tan.\,a\ \sin.\,\text{E}}{\cos.\,(\text{E}+d)}\ \text{for the forenoon.}$$

$$\text{In these, tan. } d=\frac{\sin.\,\lambda\ \tan.\,\Delta}{\text{rad.}}$$

$$\text{Tan. } a=\frac{\cot.\,\lambda\ \sin.\,d}{\sin.\,\Delta}.$$

By proceeding as in the examples of art. 65, we shall find d, and log. tan. a.

The remainder of the calculation differs in no respect from that of the first example in that article. The Table exhibiting the values of the two series E and E∓d, and the angles O, which the hour lines make with the meridian line, will be as follows:

Given λ 70° 51′, Δ 24° 6′ hence d=22° 55′, log. tan. a=9.51759			
Hours.	E	(E∓d)	Angle O
VII. P. M.	105°	82° 5′	66° 34′
VI.	90	67 5	40 12
V.	75	52 5	27 21
IV.	60	37 5	19 39
III.	45	22 5	14 6
II.	30	7 5	9 25
I.	15	7 55	4 54
XII. noon.	0	0 0	0 0
XI. A. M.	15	37 55	6 10
X.	30	52 55	15 15
IX.	45	67 55	47 47
VIII.	60	82 55	66 36

Fig. 12.

The hour lines being drawn on the dial, so as to make with the XII. o'clock line the angles in this Table, the dial will be constructed. It is represented in Fig. 12.

74. To determine the position of the hour lines by the second method, or by finding the place of the earth where the dial would be horizontal, we must determine the position of the substile in respect of the meridian, and also find the latitude and longitude of the plane.

Fig. 11.

To do this, retaining the construction of Fig. 11, let a great circle PA, passing through the pole, and perpendicular to the plane of the dial, meet it in the line OA, which will be the substile; then the angle AOH is the angle which the substile makes with the meridian, or XII o'clock hour line, the angle AOP is the elevation of the axis above the plane of the dial, and the spherical angle APH is its difference of longitude.

In the spherical triangle AHP, right angled at A, the angle AHP being equal to fHs, is measured by the arc fs; but this arc is the complement of the arc fE, which we have (art. 72.) expressed by Δ; therefore the angle AHP is the complement of Δ. Again, the arc HP is the complement of the arc Pn, which we have expressed by λ. Now we have given formulas (art. 72.) for the computation of Δ and λ; therefore the angle AHP, and the side HP of the spherical triangle, may be considered as known.

The remaining three parts of the triangle may be found from the following analogies. (See *Spherical Trigonometry.*)

Rad. : cos. H :: tan. PH : tan. AH,
Rad. : sin. PH :: sin. H : sin. AP,
Rad. : cos. PH :: tan. H : cot. P.

By substituting Δ and λ in these proportions, we find

$$\left.\begin{array}{l}\text{Tan. AH (the angle made by}\\ \text{the substile and meridian)}\end{array}\right\}=\frac{\sin.\,\Delta\ \cot.\,\lambda}{\text{rad.}}$$

$$\left.\begin{array}{l}\text{Sin. AP (the angle made by}\\ \text{the axis and substile)}\end{array}\right\}=\frac{\cos.\,\Delta\ \cos.\,\lambda}{\text{rad.}}$$

$$\text{Cot. P (the diff. of long.)}=\frac{\text{Cot.}\,\Delta\ \sin.\,\lambda}{\text{rad.}}$$

If we apply these formulæ to the example of last article, we shall find

Angle made by sub. and merid.	8° 1′
Angle made by axis and substile,	17 20
Diff. of long. of dial plane,	25 20

The dial may now be constructed as a horizontal dial for lat. 17° 20′, and as the difference of longitude is 25° 20′, which corresponds to $1^{h}\ 41\frac{1}{3}^{m}$, and the meridian of the dial plane lies to the east of the XII o'clock hour line, we must find the hour lines of $2^{h}\ 41\frac{1}{3}^{m}$, $3^{h}\ 41\frac{1}{3}^{m}$, &c. reckoned from the substile of the dial, and consider them as the hour lines of XI, X, &c. in the forenoon; also we must find the hour lines of $41\frac{1}{3}^{m}$, and on the same side of the substile as the others, and consider it as the hour line of I. The hour line of II will lie on the other side of the substile, and will correspond to $18\frac{2}{3}^{m}$. The hour line of III will correspond to $1^{h}\ 18\frac{2}{3}^{m}$ from the substile, and so on. See Fig. 12. Plate CCXXIX. Fig. 12.

75. We have, for the sake of brevity, given no geometrical construction for declining or reclining dials, because in making a dial, every thing ought, as far as possible, to be determined by calculation, and scales ought to be employed no farther than in laying down the angles. However, if any one should wish for geometrical constructions, he may readily derive them from the formulas, (art. 64. and 72.) which are very simple.

Of the time at which the Sun begins or ceases to shine on a given Plane on a given Day.

Time at which the sun begins or ceases to shine on a given plane on a given day.

76. This is a problem of some importance in dialling, because by resolving it, we learn what hour lines we ought to trace on a dial. Our limits will not allow us to enter minutely into the various cases, but we shall briefly indicate how it is to be resolved in the general case, supposing a south reclining plane declining to the west. Retaining, therefore, the construction of Fig. 11, as described in art. 72, let PS be the hour circle passing through the sun, when he is in the plane of the dial on the afternoon of a given day. In the spherical triangle HAP, we have already found AP, the measure of the angle made by the axis and substile, and the angle HPA the difference of longitude Now, in the spherical triangle SAP, right angled at A, besides AP, we know SP, the distance of the sun from the pole on the given day. Hence the angle SPA may be found by this proportion, Fig. 11.

Tan. PS : tan. PA :: rad. : cos. APS.

The angle APS expressed in time, is half the period the

Theory and Construction.

sun shines on the plane, and the hour angle HPS, in time, is the interval between noon and the sun's leaving the plane. Taking the example of art. 73, it will be found that when the sun is in the northern tropic; and consequently PS=66° 30′, the angle SPA=82° 12′. Now we found, (art. 74.) that HPA=25° 20′; therefore, when the sun sets upon the plane, SPH, the horary angle from noon is 107° 32′=7h 10m, the sum of the two arcs; and when it rises, the horary angle is 56° 52′=3h 47m, their difference. Hence it appears, that it will be needless to trace upon the dial any hour line earlier than III in the morning, or later than VIII in the evening.

Of the Line described on a Plane by the extremity of a Shadow.

Of the line described on a plane by the extremity of a shadow.

77. Sometimes we see described on dials the path described by the extremity of the shadow of the axis, in the course of the day, at certain times of the year, and in particular at the times when the sun enters the different signs of the zodiac. As this is an interesting part of the theory, we shall investigate the nature of the path of the shadow, and shew how any number of points in it may be found.

PLATE CCXXIX. Fig. 13.

Let O, (Fig. 13.) be the centre of a horizontal dial; OA the meridian line; OF the axis; and OB the shadow of the axis at any time. From F, the top of the axis, draw FD perpendicular to OB, and DA perpendicular to OB, meeting the meridian in A, and join FB, FA. Because BD is perpendicular to the two lines DA, DF, it is perpendicular to the plane of the triangle FDA, (GEOMETRY,) therefore any plane passing along BD is perpendicular to the plane of the triangle FDA, and consequently the triangle FDA is perpendicular to the plane of the dial; but the triangle FAO is also perpendicular to the same plane; therefore CA, the common section of the two triangles, is perpendicular to the plane of the dial.

Let a=OF, the length of the axis;

r=OB, the length of its shadow;

C= {the angle BOA contained by the shadow and the meridian;

v= {the angle FOB, contained by the shadow and the axis;

L=the angle FOA, the latitude;

δ= {the angle OFB, the sun's distance from the pole.

Then, in the triangles FDO, ADO, both right angled at D, we have, by TRIGONOMETRY,

OD : OF : : cos. FOD : rad.;

OA : OD : : rad. : cos. AOD;

therefore, *ex æquali* OA : OF : : cos. FOD : cos. AOD; but in the triangle OAF, OA : OF : : cos. FOA : rad.

therefore cos. FOA : rad. : : cos. FOD : cos. AOD.

From the triangle OFB we get this other proportion,

Sin. (F+O) or sin. B : sin. F : : OF : OB.

By substituting for the lines and angles in these two last proportions their symbols, we have,

Cos. L : rad. : : cos. v : cos. C

Sin. $(\delta+v)$: sin. δ : : a : r

and hence,

$$\text{Cos. } v=\frac{\text{Cos. L. cos. C}}{\text{rad.}}, \quad r=\frac{a \sin. \delta}{\sin. (\delta+v)}$$

By these formulas, having given the sun's declination, we can readily find Or, the length of the shadow, for any value of C; or combining them with the formula, of art. 39, viz. tan. C=sin. L tan. E, where E is the horary angle from noon, we can find the length of the shadow at any time of the day.

78. These two formulas may be reduced to one, by elementing the angle v; for, supposing rad.=1, we have sin. $v=\sqrt{(1-\cos.^2 \text{L} \cos.^2 \text{C})}$; and by the arithmetic of sines, sin. $(\delta+v)$=sin. δ cos. v+cos. δ sin. v. By substituting for sin. v and cos. v their values, and putting sin. δ cotan. δ for cos. δ, we get from the second formula,

$$r=\frac{a}{\text{Cos. L cos. C}+\text{cot. }\delta\sqrt{(1-\cos.^2 \text{L} \cos.^2 \text{C.})}}$$

This formula exhibits the relation between the variable angle C, and the variable line r, the length of the shadow. By giving to C any number of successive values, and substituting the value of δ (taken from the tables of the sun's declination, p. 715.) for the given day, we may find any number of points in the path of the extremity of the shadow. It is not so convenient, however, for calculation, as the formula of last article.

79. It is easy to see that the path of the extremity of the shadow must be a conic section. For the straight line drawn from the sun through the top of the stile, which determines the length of the shadow, manifestly describes, by the diurnal motion of the sun, the surface of a cone, having the axis of the dial for its axis; and the path of the shadow is a section of this cone, made by the plane of the horizon. The polar equation of the path, found in last article, shews also that the curve is a conic section; for let it be put under this form,

$$a-r \cos. \text{L} \cos. \text{C}=\cot. \delta\sqrt{(r^2-r^2 \cos.^2 \text{L} \text{ Cos.}^2 \text{C})}.$$

Now, supposing x and y to be rectangular co-ordinates, which have their origin at O, we have r cos.C=x, and $r^2=x^2+y^2$; therefore, by substituting in the equation, and squaring, &c. we get

$$\left.\begin{array}{l}(\text{Cot.}^2 \delta \sin.^2 \text{L}-\cos.^2 \text{L})x^2+2a \cos. \text{L}x \\ \quad +\cot.^2\delta\, y^2-a^2\end{array}\right\}=0.$$

This expression may, by the arithmetic of sines, be transformed to

$$\left.\begin{array}{l}-\text{Sin.}(\delta+\text{L}) \sin. (\delta-\text{L})\, x^2+2a \cos. \text{L} \sin.^2 \delta\, x \\ \quad +\text{Cos.}^2 \delta\, y^2-a^2 \sin.^2 \delta\end{array}\right\}=0.$$

If L=δ, then sin. $(\delta-\text{L})=0$, and the equation belongs to a parabola.

If L is greater than δ, so that sin. $(\delta-\text{L})$ is negative, the equation belongs to an ellipse; but if L is less than δ, so that sin. $(\delta-\text{L})$ is positive, then the equation belongs to an hyperbola. In each case, the meridian line is the transverse axis of the curve.

If $\delta=90°$, so that cos. $\delta=0$, then the term containing y^2 vanishing, x has the same value for the whole day; which shews that the path is a straight line.

The path of the shadow is an ellipse at any place within the polar circle, on the days when the sun does not set. It is a parabola at that place on the day that the sun just touches the horizon at midnight. It is a straight line at all places of the earth on the equinoctial days. And in every other case it is a hyperbola.

80. The points in which the curve crosses its axis may be readily determined from its polar equation, (art. 78.) by making C=0, and C=180°. Thus, calling their distances from the centre of the dial r' and r'', we have

$$r'=\frac{a \sin. \delta}{\sin. (\delta+\text{L})}, \quad r''=\frac{a \sin. \delta}{\sin. (\delta-\text{L})}.$$

The first of these is the length of the shadow at noon. The vertices of the curve lie on the same side of the centre of the dial, when it is a hyperbola; but on opposite sides when it is an ellipse. The other elements of the curve may be discovered in like manner, and

Theory and Construction.

then it may be traced by the methods for describing a conic section. But perhaps in practice it may be sufficient to find the points in which the curve crosses the hour lines of the dial, and then to trace it nearly correct by some mechanical contrivance. The intersection of the curve and any hour line may be found by the following geometrical construction.

Plate CCXXIX. Fig. 14.

Let O be the centre of the dial, and O XII be the meridian line (Fig. 14.). Take any two lines OM, ON, having to each other the ratio of the cosine of the latitude to radius; and on O as a centre, with these lines as radii, describe circles. Take OF in the meridian line equal to the length of the axis of the dial, and at the point F make the angle OFH equal to the sun's distance from the pole. Let OY, any hour line, meet the lesser circle in K. Through K draw KL perpendicular to the meridian, meeting the greater circle in G. Draw OG, meeting FH in H. In the hour line OY, take OB equal to OH, and B is the point in which the hour line meets the path of the shadow.

For, by trigonometry, OG : OK :: sin. OKL : sin. OGL :: cos. KOL : cos. GOL; that is, (because the angle KOL or YOL$=$C) rad. : cos. L :: cos. C : cos. HOL; hence HOL is the angle we have denoted by v in the first of the two formulas, art. 77. Now the angle F$=\delta$, and OF$=a$; and sin. H : sin. F :: OF : OH; that is, sin. $(\delta+v)$: sin. δ :: a : OH, hence OH has the value of r in the second formula; and consequently OB$=$OH is the length of the shadow. Whatever has been said respecting the shadow on a horizontal dial will apply to any dial whatever, if L be put for the latitude of the place where the dial would be horizontal, and if we take the substile as the meridian.

Retrogradation of the Shadow.

Retrogradation of the shadow.

81. The shadow which is projected on a dial by the edge of a stile or axis directed to the pole, revolves about the centre always the same way. The hour may also be indicated by the shadow of a single point of the axis, which may be the summit of an upright wire, as explained in art. 41, and then the shadow will proceed, not from the centre, but from the bottom of the wire. The shadow on a horizontal dial for any latitude out of the torrid zone, with a stile of this construction, will also move always the same way; but at any place between the equator and tropics, there is a period of the year when the shadow moves forward, until it reaches a certain limit, and then it moves back again. This is what is called the *retrogradation* of the shadow.

Fig. 15.

To see how this may happen, let O (Fig. 15.) be the centre of a horizontal dial, and OF the axis; and let FA be a vertical rod, which meets the axis at F. The shadows of the material lines OF, AF, will form a triangle OfA on the surface of the dial, the vertex of which, f, will trace a curve $f\,f'\,f''\,f'''$, which in general will be an hyperbola. In the temperate zone, the point A always falls within the curve, but at any place between the equator and either tropic, when the sun passes between the zenith and the elevated pole, the point A falls without the hyperbola, so that straight lines Af', Af''' may be drawn from it to touch the curve. Now at the instant of sun-rise, the two shadows Of, Af will be parallel to one of the asymptotes; and as the day advances, their intersection f will move along the curve, arriving first at f', the point in which the tangent meets the curve, next at the vertex f'', and then proceeding along $f''\,f'''$, the other branch. Now by this motion of the point f, the shadow Af will turn about the point A in a direction from O to f'; but when it has arrived at the position Af', it will be for a moment stationary; as the intersection f advances to f'', the vertex, the shadow will evidently turn back; and when f arrives at f'', the shadow will coincide with the axis. A like phenomenon will be exhibited in the afternoon. The shadow will at first recede from the axis, until it coincide with the tangent Af'''; and then it will again approach the axis until it vanish at sun-set, and at that instant it will be parallel to the other asymptote.

All this may be observed on a dial in any latitude, provided its plane pass between the sun and the equator at noon, and the hour be shewn by a stile perpendicular to its plane.

The phenomenon we have been describing will appear very simple to the mathematician, and perhaps hardly worthy of particular notice; it seems, however, to have excited attention, probably because of the apparent solution it affords to the return of the shadow on the sun-dial of Ahaz. But this explanation is not admissible, because in that case, the return of the shadow must have been a thing altogether miraculous, otherwise it would not have excited attention.

Meridian of Mean Time.

Meridian of mean time.

82. The hour of the day indicated by a good sun-dial will agree with that shewn by a clock only on certain days of the year; in general, there will be a difference, which is called the *Equation of time.* The nature and quantity of this correction has been fully explained in ASTRONOMY, p. 652; and a Table given in page 797, by which it may be accurately found.

A line may be traced upon the plane of a dial, in such a manner, that the extremity of the shadow of the stile shall fall on it at the instant of *mean* noon, which will thereby be indicated just as the time of *apparent* noon is shewn by the shadow of the edge of the stile falling on the meridian line. The line which shews the time of mean noon is called the *meridian of mean time.* Its figure and position on a horizontal dial is shewn in Plate CCXXVIII. Fig. 9.

Plate CCXXVIII. Fig. 9.

To trace the meridian of mean time, the hour lines for 16 minutes before, and the same period after noon, should be found, and lines drawn from the centre to divide the angles which they make with the meridian into as many equal parts as may be thought necessary; for example, 96 lines may be drawn, and these will correspond, with sufficient accuracy, to portions of time, differing by 10 seconds one from another. But in some declining dials, the angular motion of the shadow at noon may deviate considerably from uniformity, and then it may be necessary to find the correct position of the hour lines for every fifth minute between apparent and mean noon.

The path of the shadow is next to be traced for as many different days of the year, equally distant, as may be thought necessary; and the point in which the path of the shadow cuts the hour line corresponding to the equation of time of any day will be a point in the meridian of mean time for that day. In this manner may any number of points be found, and a line traced through them; and the days of the year being marked opposite to them, the meridian of mean time will be finished.

The first who has spoken of a meridian of mean time was M. De Fouchy, of the Academy of Sciences, before the year 1740. The republic of Geneva had one traced in 1780; and the instant of mean noon was made known by a signal from the church of St Peter, to enable the watch-makers to regulate their instruments to mean time.

Dials with variable centres.

Dials with Variable Centres.

83. Dials of this kind, although not common, nor very convenient, are yet curious, and deserve to be known, on account of the elegance of their mathematical theory. This may be deduced from the following proposition, which seems to be one of the class called by Geometers, *Porisms.*

A system of hour points may be found on a plane, such, that for every day in the year (or any time in which the sun's declination may be regarded as constant) there is a point in the meridian line at which, if a stile be placed in the plane of the meridian, so as to make with the horizon any given angle, its shadow shall pass through the different hour points at the instants of time corresponding to them, and in this way shew the time of the day.

In order to investigate the truth of this proposition, we shall resolve the following problem.

Problem. Having given the sun's declination, and the time from noon, and also the latitude of a place, to find the angle which the shadow of a stile makes with the meridian line on a horizontal plane, supposing the stile to lie in the plane of the meridian, and to make with the horizon a given angle.

Plate CCXXIX. Fig. 16.

Let LMN be the horizon, LPN the meridian, P the pole, CQ the stile, which meets the meridian in the heavens at Q; let S be the sun in the hour circle PS, and MSQX a great circle passing through S and Q, and cutting the plane of the horizon in the line MCX.

Put λ for PN, the given latitude;

ε for QN, the given elevation of the stile;

δ for the comp. of PS, the sun's given dec.

ϕ for QPS, the given hour angle;

ψ for the angle LQM;

θ for the angle XCN or arc LM, which is to be found.

By *Spherical* Trigonometry, if a and b be the sides of a spherical triangle, C the angle they contain, and A the angle opposite to a, then

$$\text{Cot. A sin. C}+\text{cos. C cos. } b=\text{cot. } a \text{ sin. } b.$$

Also in a right angled spherical triangle, if a and b be the sides about the right angle, and A the angle opposite to a,

$$\text{Cot. } a \text{ sin. } b=\text{cot. A}.$$

In the first of these two formulas, let $PS=90-\delta$, and $PQ=\varepsilon-\lambda$ be put for a and b; also $P=\phi$ for C, and $SQP=180^o-\psi$ for A, and we get

$$-\text{cot. }\psi \text{ sin. }\phi+\text{cos. }(\varepsilon-\lambda)\text{ cos. }\phi=\text{sin. }(\varepsilon-\lambda)\text{ tan. }\delta;$$

and in the second let sin. QL=sin. ε be put for sin. b, and $LM=\theta$ for a, also $LQM=\psi$ for A, and the result will be

$$\text{Cot. }\theta\text{ sin. }\varepsilon=\text{cot. }\psi.$$

Let this value of cot. ψ be substituted instead of it in the preceding equation, and we shall get, by transposition and division,

$$\text{Cot. }\theta=\frac{\text{Cos. }(\varepsilon-\lambda)\text{ cos. }\phi-\text{sin. }(\varepsilon-\lambda)\text{ tan. }\delta}{\text{sin. }\varepsilon\text{ sin. }\phi}.$$

From this formula, we may find the value of θ, the angle made by the shadow and the meridian, as required.

Fig. 17.

84. Let us now suppose that Fig. 17 represents any dial with a moveable centre, O XII being the meridian line; XI, X, &c. the forenoon hour points; and I, II, &c. the afternoon hour. Also let C be the position of the bottom of the stile, on any given day; and A any hour point; join AC, then AC will be the position of the shadow of the stile corresponding to the hour point A on that day. Therefore if we recur to the notation employed in the solution of the problem in last article, and express the time from noon by ϕ, then the angle at C will be θ, and so we shall have

$$\text{Cot. C}=\frac{\text{Cos. }(\varepsilon-\lambda)\text{ cos. }\phi-\text{sin. }(\varepsilon-\lambda)\text{ tan. }\delta}{\text{Sin. }\varepsilon\text{ sin. }\phi}.$$

Draw AB perpendicular to the meridian; put $OB=x$, and $AB=y$, (so that x and y are the co-ordinates of any hour point,) and put v for OC, the variable distance of the bottom of the stile from the fixed point O, in the plane of the dial; then $BC=x-v$; and because AB : BC : : rad.: cot. C, that is $y : x-v : : 1 :$ cot, θ, we have

$$\text{cot. }\theta=\frac{x-v}{y},\text{ and}$$

$$\frac{x-v}{y}=\frac{\text{Cos. }(\varepsilon-\lambda)\text{ cos. }\phi-\text{sin. }(\varepsilon-\lambda)\text{ tan. }\delta}{\text{Sin. }\varepsilon\text{ sin. }\phi};$$

and hence we find,

$$v=\left\{\begin{array}{l}\dfrac{x\text{ sin. }\varepsilon\text{ sin. }\phi-y\text{ cos. }(\varepsilon-\lambda)\text{ cos. }\phi}{\text{Sin. }\varepsilon\text{ sin. }\phi}\\[2ex] +\dfrac{y\text{ sin. }(\varepsilon-\lambda)}{\text{sin. }\varepsilon\text{ sin. }\phi}\text{ tan. }\delta.\end{array}\right.$$

The nature of the dial requires that the position of the stile should depend entirely on the sun's declination, without any regard to a particular hour of the day; and also that the position of the hour points should depend entirely on the hour of the day, without any regard being had to the sun's declination: But these two conditions will manifestly be satisfied, if, in the last equation, we make

$$x\text{ sin. }\varepsilon\text{ sin. }\phi-y\text{ cos. }(\varepsilon-\lambda)\text{ cos. }\phi=0;$$

and at the same time put

$$\frac{y\text{ sin. }(\varepsilon-\lambda)}{\text{Sin. }\varepsilon\text{ sin. }\phi}=a,\text{ a constant quantity,}$$

for then we shall have x and y both independent of δ, the declination, and $v=a$ tan. δ a quantity independent of ϕ, as they ought to be.

By resolving our two assumed equations in respect of x and y, we readily find

$$x=a\frac{\text{Cos. }(\varepsilon-\lambda)}{\text{Sin. }(\varepsilon-\lambda)}\text{cos. }\phi\;.\;.\;.\;.\;.\;(A)$$

$$y=a\frac{\text{Sin. }\varepsilon}{\text{Sin. }(\varepsilon-\lambda)}\text{sin. }\phi\;.\;.\;.\;.\;.\;(B)$$

$$v=a\text{ tan. }\delta.\;.\;.\;.\;.\;.\;.\;.\;.\;.\;.\;.\;(C)$$

These three equations express completely the nature of every dial of this kind, and are sufficient for its construction, nothing more being necessary than to assume for a a line of any length whatever, as a scale on which the parts of the dial are to be measured; then to compute x and y from the formulas (A), (B), by making $\phi=15^0$ for the hour lines of XI and I, and $\phi=30^0$ for those of X and II, and so on; and lastly, to form a graduated scale along the meridian line, proceeding both ways from O, that point being the position of the stile at the time of either equinox: And as, by considering Fig. 34, it will readily appear that for any given hour the angle θ, (or C on the dial,) ought to increase as the sun approaches the north pole; the scale of declination for the north side of the equator must lie on the north side of O, and that for the south side of the equator on the south side of O. The months and days of the year ought also to be placed on the scale opposite to the degrees of declination to which they correspond.

85. From the equations (A) (B), of last article, we find,

$$x^2=\frac{a^2\text{ cos.}^2\,(\varepsilon-\lambda)}{\text{Sin.}^2\,(\varepsilon-\lambda)}\text{cos.}^2\,\phi,$$

Theory and Construction.

$$\frac{y^2 \cos.^2 (\varepsilon-\lambda)}{\text{Sin.}^2 \varepsilon} = \frac{a^2 \cos.^2 (\varepsilon-\lambda)}{\sin.^2 (\varepsilon-\lambda)} \sin.^2 \phi ;$$

Hence, by adding we find,

$$x^2+\frac{y^2 \cos.^2 (\varepsilon-\lambda)}{\sin.^2 \varepsilon}=\frac{a^2 \cos.^2 (\varepsilon-\lambda)}{\sin.^2 (\varepsilon-\lambda)} \ldots \text{(D)}.$$

But this equation manifestly belongs to an ellipse, the co-ordinates to the axes of which are x and y; hence we have an elegant property of the hour points on these dials, namely, that they are all in the perimeter of an ellipse, of which

$$\left.\begin{array}{l} \text{The merid. semi-axis} = \dfrac{a \cos. (\varepsilon-\lambda)}{\sin. (\varepsilon-\lambda)} \\ \text{The other semi-axis} = \dfrac{a \sin. \varepsilon}{\sin. (\varepsilon-\lambda)} \end{array}\right\} \ldots \text{(E)}$$

The Analemmatic or Azimuth Dial.

The analemmatic or azimuth dial.

86. The analemmatic dial is constructed on the principles which we have explained, art. 83—86. Its stile is vertical; therefore recurring to the notation and formulas of these articles, we have $\varepsilon=90^\circ$; and hence the equations of the dial are,

$$x=a \tan. \lambda \cos. \phi ;$$
$$y=a \sec. \lambda \sin. \phi ;$$
$$v=a \tan. \delta.$$

The dimensions of the ellipse which passes through its hour points, are these,

Semiconj. or merid. axis $=a$ tan. λ;
Semitransverse axis . . $=a$ sec. λ;
Eccentricity . . . . . $=a$.

Plate CCXXX. Fig. 1.

The values of x, y, v, are all the elements wanted to construct the dial, either arithmetically or geometrically. The geometrical construction may be as follows. See Fig. 1.

1. Draw two straight lines Aa, Bb, intersecting each other at right angles in O.

2. In OA, one of these lines, take OD of any suitable length for the eccentricity of the dial; and at the point D draw DB, so as to make with DO an angle equal to the latitude of the place. Then OB shall be half the lesser axis, and B the 12 o'clock hour point.

3. In OD take OA and Oa, each equal to DB; and Aa shall be its greater axis, and Aa the six o'clock hour points.

4. On O as a centre, with OA and OB as radii, describe circles, and divide the quadrants that are in the same angle, each into six equal parts, as in the Figure.

5. From K, any one of the points of division in the outer circle, draw KL perpendicular to OA; and from k, the corresponding point in the inner circle, draw kN parallel to OA, meeting KL in N, which will be one of the hour points, and in the same way may all the others be found, as is shewn in the Figure.

6. At the point D make angles ODE, ODe each $23\frac{1}{2}$ degrees, the sun's greatest declination; and E, e, shall be the positions of the bottom of the stile, at the summer and winter solstices, the former lying on the north, and the latter on the south side of O, the middle of the dial.

7. Describe a circle with DO as a radius, and find the tangents of the series of arcs, 1°, 2°, 3°, &c. to 23° of that circle, and lay them as a scale from O to E, and e in each side of O.

8. Find in the Tables, p. 715. the sun's declination on the first day of every month, and mark the beginning of the month on the scale Ee, opposite to its corresponding degree of declination. As many of the intermediate days as there may be room for, may in like manner be marked on the scale.

9. The stile must now, by some mechanical contrivance, be placed over the scale so as to admit of being moved along it, and set to any day, and the dial is finished.

To prove that the hour points have their proper position, let x=LN, y=OL, ϕ=angle HOK; then because

rad. : cos. ϕ : : KO : KL : : kO ($=a$ tan. λ) : NL($=x$),
and rad. : sin. ϕ : : KO ($=a$ sec. λ) : OL ($=y$)
we have $x=a$ tan. λ cos. ϕ, and $y=a$ sec. λ sin. ϕ, as they ought to be.

This dial was given by Vaulezard, in 1644, in a French work called *Traité de l'origine, Demonstration, Construction, et Usage du Quadrant Analemmatique.* It made also the principal object of Forster's *Elliptical Horologiography*, published at London, in 1654. It is sometimes joined to horizontal dials, to which it is an elegant appendage; because the shadows on the two dials can, in general, only indicate the same hour, when both stiles are in the plane of the meridian; and hence the compound dial can be placed in a proper position, without the help of a compass or meridian line. Fig. 2. represents a dial of this construction. It has the advantage of not being subject to the error of refraction. Plate CCXXX. Fig. 2.

Lambert's Dial.

Lambert's dial.

87. M. Lambert remarked in the Berlin Ephemerides for 1777, that a dial, with a moveable centre, might be constructed, in which the hour points should stand at equal distances, on the circumference of a circle. It is easy to see that this is possible; for the general expressions (E), for the semiaxes of the ellipse in which the hour points are situated in this kind of dial, being, by art. 85,

$$\frac{a \cos. (\varepsilon-\lambda)}{\sin. (\varepsilon-\lambda)}, \quad \frac{a \sin. \varepsilon}{\sin. (\varepsilon-\lambda)} ;$$

if we suppose ε, the elevation of the stile, to be such that cos. $(\varepsilon-\lambda)$=sin. ε; the axes of the ellipse will be equal, and it will become a circle. This condition requires that $\varepsilon-\lambda+\varepsilon=90^\circ$; from which we find,

$$\varepsilon=\tfrac{1}{2} (90+\lambda) ;$$
$$v=a \tan. \delta ;$$
$$\text{rad. of dial}=a \tan. \tfrac{1}{2} (90+\lambda).$$

In the latitude of Edinburgh, which is $55^\circ 58'$, the elevation of the stile of a dial of this kind would be $\frac{1}{2}(90^\circ+55^\circ 58')=72^\circ 59'$. The geometrical construction of this dial is extremely simple.

1. Take a straight line OD (Fig. 3.) of any length, and at O one of its extremities draw OB perpendicular to it. Fig. 3.

2. At the point D, make the angle ODB equal to half the sum of 90°, and the latitude of the place; and OB will be the radius of the dial.

3. Describe a circle on O as a centre, and divide each quadrant into six equal parts, and the points of division will be the hour points of the dial.

4. Draw two lines DE, De, and make a scale of tangents of the sun's declination from O to E and e, and against the divisions of the scale write the days of the month, as described in the analemmatic dial.

5. Place the stile over the meridian, so that it may admit of being adjusted to the time of the year exactly, as in the analemmatic dial, and so that it may make with the horizon an angle equal to BDO, and the dial will be constructed.

Note. The style must be on the north or south side of the point O, according as the sun is on the north or south side of the equator.

If the shifting of the position of the stile in these di-

Description of Dials.

als should be considered an inconvenience, it may be avoided, by putting different sets of hour points on the dial, corresponding to different times of the year, just as if the hour points were shifted, so as to suit the style, instead of adapting the style to the position of the hour points.

Having now explained the general theory of dials, as well as the most common and useful of them, upon strictly geometrical principles, we shall now describe some others; but the limits of our work will not allow us to enter so minutely into the mathematical investigation.

Portable Dial on a Card.

Portable dial on a card.

Plate CCXXX. Fig. 4, 5.

88. This dial is represented in Figs. 4. and 5. Its geometrical construction is as follows:

1. Draw a straight line 12 CA parallel to the top of the card, (Fig. 4.) and draw another line kC6, bisecting the former at right angles. On C as a centre, with any convenient radius, describe a semicircle 12, 6, A, and divide it into twelve equal parts at the points 11, 10, 9, 8, &c.

3. From the points 11, 10, 9, 8, &c. draw lines perpendicular to the diameter 12 A; and these will be the hour lines. The half hours and quarters may also be drawn, by dividing each arc into four equal parts.

4. At 12, the extremity of the diameter, draw a line 12 k, to make with 12CA an angle equal to the latitude of the place; let this line meet the 6 o'clock hour line in k, through which draw a line BkD perpendicular to 12k.

5. At the point 12, draw lines 12B, 12D, to make each, with 12k, an angle of 23½ degrees, the sun's greatest declination. These lines determine the length of BD, the scale of the months.

6. Describe a semicircle on BD as a diameter, divide it into six equal parts at H, I, K, L, M, and draw lines Hh, Ii, Kk, Ll, Mm, perpendicular to BD. These points are the centres of the arcs of the signs.

7. On B and D as centres, describe arcs 12 ♑, 12 ♋, to pass through the point 12, and these will be the tropics. Also on h and m as centres, describe arcs to pass through 12, and the one will be the arc of the signs ♒ and ♐, and the other the arc of the signs ♊ and ♌. And on i and l as centres, describe arcs through 12, and the one will be the arc of the signs ♓ and ♏, and the other the arc of the signs ♍ and ♉. And lastly, describe an arc on k as a centre, to pass through 12, and it will be the arc of the signs ♈ and ♎.

8. On the point 12 as a centre, describe an arc of a circle OPQ, terminating in the lines 12B, 12D, and divide each half PO, PQ, into 23½ equal parts; then the arc OPQ is a scale of the sun's declination.

9. Find from a table the sun's declination for every 5th day of the year, and laying a ruler over the point 12 and the degree of each day, on the scale OQ, mark the point in which the ruler meets BD; and against the points of division for the days of each month write the name of the month, (see Fig. 5.) observing, that the days from 21st March to 23d September must lie on the left hand side of k, the middle of the scale.

Fig. 5.

10. Cut a slit through the card along the line BD, and through it put a thread, having a bead sliding along it, and a plummit at one end, which hang along the face of the dial when it is held vertically, and make a knot on the other end of the thread at the back of the dial, so that it may not be drawn through the slit.

11. Draw a line N v parallel to CA, and at one end of the line cut slits along vx, xy, yz, three sides of a rectangle, through the card, so as to admit of its turning about the remaining side vz as a hinge. This rectangle is the *gnomon* of the dial, and the line VN is the shadow line. The manner of placing the hours conveniently against the hour lines, and forming the scale of months, will easily be understood by inspecting Fig. 5, which shews the dial completely finished.

89. To rectify the dial, set the thread in the slit right against the day of the month, and stretch it over the angular point where the circles meet at XII, then shift the bead to that point of the thread, and the dial is rectified.

To find the hour of the day, raise the gnomon, (no matter how much or how little,) and hold the edge of the dial next the gnomon towards the sun, so that the uppermost edge of the shadow of the gnomon may just cover the *shadow line*; and the bead then moving freely on the face of the dial by the weight of the plummet, will shew the time of the day among the hour lines as it is forenoon or afternoon.

Note. The dial will evidently indicate the hour, but imperfectly, near noon; but it does not seem that this evil can be avoided in an altitude dial.

To find the time of sun rising and setting. Having rectified the dial for the given day, move the thread among the hour lines, until it either covers some one of them, or lies parallel betwixt any two, and then it will cut the time of sun rising among the forenoon hours, and the time of sun setting among the afternoon hours.

To find the sun's declination, stretch the thread from the day of the month over the angular point at XII. and it will indicate the declination on the graduated arch.

To find on what days the sun enters the signs. When the bead, as above rectified, moves along any of the curve lines, which have the signs of the zodiac marked upon them, the sun enters those signs on the days pointed out by the thread in the scale of months.

Montucla, in his *Mathematical Recreations*, says, that this dial originated from an universal rectilineal dial constructed by Father de Saint-Rigaud, a Jesuit, and professor of mathematics in the college of Lyons. He also observes that it is generally called the Capuchin, because it resembles the head of a Capuchin friar with the cowl inverted.

Dial on a Cylinder.

Dial on a cylinder.

Plate CCXXX. Fig. 6.

90. This dial is shewn in Fig. 6. It indicates the hour of the day, the sun's place in the ecliptic, and his altitude at any time of observation. The dial is constructed by tracing the lines on paper, and pasting it round the surface of the cylinder. The lines may be drawn by the following rules:

Fig. 7.

1. Draw a line AaB (Fig. 7.) parallel to the top of the paper, and on a as a centre, with any convenient radius, describe the quadrantal arc AE, and divide it into 90 equal parts or degrees.

2. Draw AC perpendicular to AB, touching the quadrant at A, and from a draw lines through as many degrees of the quadrant as are equal to the sun's altitude at noon on the longest day of the year, at the place for which the dial is to serve, (this is always equal to the sum of 23½ degrees, and the complement of the latitude,) and continue those lines until they meet the tangent AC; from the points of intersection draw lines across the paper parallel to AB, and they will be the parallels of the sun's altitude in whole degrees, from sunrise to sunset, on all the days of the year. (In the Figure, we have only drawn every fifth degree. These lines must be drawn out to the right line BD, which

Description of Dials.

must be parallel to AC, and as far from it as is equal to the intended circumference of the cylinder.

Dial on a cylinder.

Plate CCXXX. Fig. 6, 7.

3. Divide the space between AC and BD (at the top and bottom) into 12 equal parts, for the signs of the ecliptic, and from mark to mark of these divisions draw lines, which will be parallel to AC and BD, and place the characters of the twelve signs on these twelve spaces at the bottom, as in the Figure. The spaces between the signs may be subdivided into halves, and, if there be room, into quarters.

4. At the top of the dial, make a scale for the months and days of the year, so as the days may stand over the sun's place for each of them, in the signs of the ecliptic. The sun's place must be taken from an ephemeris.

5. Compute the sun's altitude for every hour, in the latitude of your place, when it enters each sign of the ecliptic, and also when it is in the middle of the sign, and in the upright parallel lines at the beginning and middle of each sign, make marks for those computed altitudes among the horizontal parallels of altitude, reckoning them downwards, according to the order of the numeral figures set to them at the right hand, answering to the like division of the quadrant at the left, and through these marks draw the curve hour lines, and set the hours to them, as in the Figure, reckoning the forenoon hours downward, and the afternoon hours upward. The sun's altitude should also be computed for the half hours; and the quarter hour lines may be drawn very nearly in their proper places by estimation and accuracy of the eye. Then cut off the paper at the left hand close by the line AC, and also the paper on the right hand close by the line BD, and cut it also close by the top and bottom horizontal lines, and it will be fit for pasting round the cylinder.

This cylinder (Fig. 7.) should be hollow, to hold the stile DE when it is not used. The crooked end of the stile is put into a hole in the top AD of the cylinder, and the top goes on tightish, but must be made to turn round on the cylinder like the lid of a paper snuff box. The stile must stand straight out, perpendicular to the side of the cylinder, just over the right line AB, where the parallels of the sun's altitude begin; and the length of the stile, or distance of its point *c* from the cylinder, must be equal to the radius *a*A of the quadrant. (Fig. 7.)

91. To use this dial, place the horizontal base BC of the cylinder on a level table, where the sun shines, and turn the top AD, till the stile stands just over the day of the then present month. Then turn the cylinder about on the table, till the shadow of the stile falls on it, parallel to those upright lines which divide the signs; that is, till the shadow be parallel to a supposed axis in the middle of the cylinder, and then the point, or lowest shadow, will fall upon the time of the day as it is before noon or afternoon, among the curve hour lines, and will shew the sun's altitude at that time among the cross parallels of his altitude, which go round the cylinder, and at the same time it will indicate the sign of the ecliptic in which the sun is. The degree of the sign may be estimated nearly by the eye.

The dial may also be suspended by the ring F at the top, and when it is not used, the stile may be drawn out, and put into the cylinder.

Ring Dial.

Ring dial.

91. Ring dials are another variety of the kind that indicates the hour by the sun's altitude. They are very common; but those generally sold are inaccurate in the principle of their construction, for the hours are usually marked in the inside on one line, and a narrow moveable band, with a hole in it, is shifted till the hole correspond with the degree and sign of the sun's place marked on the outside. Instead of one circle, there ought to be seven distinct circles on the concave surface of the ring, to represent as many parallels of the sun's entrance into the signs; and on each, there must be marked the sun's altitude on its entrance into the sign belonging to the parallel to which the circle corresponds. When these points are marked, they must be joined by curves, which will be the real hour lines.

Plate CCXXX. Fig. 8.

Having provided a ring (Fig. 8.), or rather described a circle of the same size as the ring which is to be divided, and having fixed on B as the point of suspension, make BA and BO, on each side of B, equal to the latitude of the place; that is, equal to the distance of the zenith from the equator. Then through the points A and O draw the chord AO, and AD perpendicular to it: If the line A 12 be then drawn through A, and the centre of the circle, the point 12 will be the hour of noon on the day of the equinox.

To find the other hour-points for the same day at the commencement of Aries and Libra; from the centre A describe the quadrant OD; and from O set off towards P, the sun's altitude at different hours of the day; as at 1 and 11, 2 and 10, &c. The lines drawn from the centre A through these points of division, if continued to the circumference of the circle B 12 A, will give the hour-points of the day of the equinox.

To obtain the hour-divisions on the circles corresponding to the other signs; first set off on both sides of the point A (Fig. 9.), the sun's declination when he enters each of the signs, viz. the arcs AE and AI of 11° 30′ for the commencement of Taurus or Virgo, of Scorpio or Pisces; AF of 20° 13′ for the commencement of Gemini and Leo; AK equal to it for the commencement of Sagittarius and Aquarius; and AG and AL of 23° 30′ for the commencement of Cancer and Capricorn. Fig. 9.

Now, to find the hour-points on the circle, that corresponding to the commencement of Aquarius, for example; through the point K, which corresponds to the sun's entrance into that sign, draw KP parallel to AO, and also the line K 12: From the same point K describe between K 12, and the horizontal line KP, the arc QR, on which set off from R towards Q, the sun's altitude at the different hours of the day when he enters Sagittarius and Aquarius, as seen in the Figure; and if lines be drawn from K to these points of division, you will have the hour-points of the two circles corresponding to the commencement of Sagittarius and Aquarius. By proceeding in the same manner for the sun's entrance into the other signs, you will have the hour-points in the circles which correspond to them.

Then trace out on the concave surface of the circles seven parallel circles (Fig. 10.), that in the middle for the equinoxes; the two next on each side for the commencement of Taurus and Virgo, Scorpio and Pisces; the following two on the right and left for Gemini and Leo, Sagittarius and Aquarius; and the last two for Cancer and Capricorn: If the similar hour-points be joined by a curve line, the ring dial will be completed. Fig. 10.

The next thing to be done, is to adjust properly the hole which admits the solar rays; for it ought to be moveable, so that on the day of the equinox it may be at the point A; on the day of the summer solstice at G; on the day of the winter solstice at L; and on the other days of the year in the intermediate positions. For this purpose, the exterior part of the ring must

Description of Dials.

have in the middle of it a groove, to receive a small moveable ring with a hole in it. The divisions K, L, I, A, E, F, G must be marked on the outside of this part of the ring by parallel lines, inscribing on one side the ascending signs, and on the other the descending. When this construction has been made, it will be easy to place the hole of the moveable part A in the proper division; or at some intermediate point; for if the ring be pretty large, each sign may be divided into two or three parts.

To know the hour; move the hole A to the proper division, according to the sign and degree of the sun's place; then turn the instrument in such a manner, that the sun's rays passing through the hole may fall on the circle corresponding to the sign in which the sun is: the division on which it falls will shew the hour.

To render the use of this instrument easier, instead of the divisions of the signs, the days on which the sun enters them might be marked on it. For example, June 21. instead of ♋, &c.

Universal Dial on a Cross.

Universal dial on a cross. Plate CCXXX.

90. A dial is said to be *universal*, when, by adjustment, it indicates the hour in any latitude whatever. The equinoctial dial described in art. 37. is of this kind, for, from its construction, it can readily be adjusted to any latitude whatever.

Fig. 11.

The universal dial on a cross is represented by Fig. 11. It is moveable on a joint C, for elevating it to any given latitude on the quadrant CO *g o*, as it stands upon the horizontal board A. The arms of the cross stand perpendicular to the middle part; and the top of it, from *a* to *n*, is equal in length to either of the arms *n e* or *m k*.

Having set the middle line *t u* to the latitude of your place on the quadrant, the board A level, and the point N northwards by the needle, (allowing for the variation); the plane of the cross will be parallel to the plane of the equator; and the dial will be adjusted. Then from III o'clock in the morning till VI, the upper edge *k l* of the arm will cast a shadow on the time of the day on the side of the arm *c m*; from VI till IX, the lower edge *i* of the arm *i o* will cast a shadow on the hours on the side *o q*. From IX till XII at noon, the edge *a b* of the top *a n*, will cast a shadow on the hours on the arm *n e f*. From XII till III in the afternoon, the edge *c d* of the top part will cast a shadow on the hours on the arm *k l m*; from III to VI in the evening, the edge *g h* will cast a shadow on the hours on the parts *p s*; and from VI till IX, the shadow of the edge *e f* will shew the time on the top *a n*.

The breadth of each part *a b*, *e f*, &c. must be so great as never to let the shadow fall quite without the part or arm on which the hours are marked, when the sun is at his greatest declination from the equator. The shadow will always fall within the arm *e f*, making its length *n e* the radius of a circle, the breadth *e f* exceed the tangent of $23\frac{1}{2}°$ of that circle; that is, it ought not to be less than about $\frac{44}{100}$ parts of the length: but that the shadow may fall within the quarter divisions of the hours when it comes near the end of the arm, it ought to be almost double that breadth.

As the cross lies in the plane of the equinoctial, the dials on its arms will be horizontal dials for the equator, and those on its sides east and west dials there. Hence the hour lines may be found as follows:

Lay the cross on a sheet of paper, and trace its shape, as in Fig. 12, with a black-lead pencil. Then on *a*, a corner of one of the arms with a radius equal to *a e*, the length of the arms, describe the quadrantal arc *e f*. Divide the quadrant into six equal parts at *g h i*, &c. and draw lines from *a* through the points of division to meet the arm in 1, 2, 3, and these are all the hour-lines that can fall upon it. Divide each of the other arms for the three hours it contains in the same manner; and set the hours to the sides of the arms in their proper places, as marked in Fig. 11. The divisions for the quarter hours may be found, by dividing the arcs *e g*, *g h*, *h i* into four equal parts.

Description of Dials. Plate CCXXX. Fig. 12. Fig. 11.

An Universal Dial, shewing the Hours by a Terrestrial Globe, and by several Gnomons.

91. This dial, which seems to have been invented by the very ingenious Mr James Ferguson, may be made of a thick square piece of wood, or hollow metal. The sides are cut into semicircular hollows, in which the hours are placed: The stile of each hollow coming out from the bottom thereof, as far as the ends of the hollows project. The corners are cut into angles, in the insides of which the hours are also marked; and the edge of the end of each side of the angle serves as a stile for casting a shadow on the hours marked on the other side.

Universal dial, shewing the hours by a terrestrial globe, and by several Gnomons. Plate CCXXX. Fig. 14.

In the middle of the uppermost side or plane there is an equinoctial dial: in the centre whereof an upright wire is fixed, for casting a shadow on the hours of that dial, and supporting a small terrestrial globe on its top.

The whole dial stands on a pillar, on the middle of a round horizontal board, in which there is a compass and magnetic needle, for placing the meridian stile towards the south. The pillar has a joint with a graduated quadrant upon it, (supposed to be hid from sight under the dial in the Figure,) for setting it to the latitude of any given place.

The equator of the globe is divided into 24 equal parts, and the hours are laid down upon it at these parts. The time of the day may be shewn by these hours, when the sun shines upon the globe.

To rectify and use this dial, set it on a level table, or sole of a window, where the sun shines, placing the meridian stile due south, by means of the compass needle, making allowance for its variation; or better, by means of a meridian line drawn upon the side of the window. Then bend the pillar in the joint till the axis of the upper dial make with the plane of the horizon an angle equal to the latitude of the place, as measured on the quadrant. When the machine is thus rectified, its plane will be parallel to the equator, and the axis that supports the globe will point to the north pole of the heavens. The same hour will then be shewn in several of the hollows, by the ends of the shadows of their several stiles. The shadow of the axis of the globe will shew the hour on the equinoctial dial, from the 20th of March to the 22d of September; and if the meridian of the place on the globe be set even with the meridian stile, all the parts of the globe that the sun shines upon will answer to those places of the real earth which are then enlightened by the sun. And if the hour of VI be marked on the equator in the meridian of your place, the division of the light and shade on the globe will shew the time of the day.

The construction of this dial is as follows: on a thick square piece of wood, or metal, draw the lines *a c* and *b d*. (Fig. 14.) as far from each other as you in- Fig. 14.

Description of Dials.

tend the thickness of the stile $a\,b\,c\,d$; and in the same manner draw the like thickness of the three other stiles $e\,f\,g\,h$, $i\,k\,l\,m$ and $n\,o\,p\,q$, all standing outright as from the centre.

Plate CCXXX. Fig. 14.

On a as a centre, with any convenient radius a A (which leaves proper strength of stuff when KI is equal to a A) describe the quadrantal arc A c; and with the same radius, on b as a centre, describe the quadrantal arc d B. All the quadrantal arcs in the Figure are to be described with the same radius, and in the same manner, on their centres $e\,f$, $i\,k$, and $n\,o$, and each quadrant is to be divided into six equal parts, for as many hours as in the Figure, each of which may be subdivided into four for the half hours and quarters. At equal distances from each corner, draw the right lines I P and Kp, L q and M q, N r and O r, P s and Q s, to form the four angular hollows I p K, L q M, N r O, and P s Q, making the distances between the tips of the hollows, as IK, LM, NO and PQ, each equal to the radius of the quadrants, and leaving room within the angular points p, q, r, and s, for the equinoctial circle in the middle.

To divide the insides of these angles properly for the hour spaces thereon; on K and I as centres, with KI as a radius, describe the arcs K t, I t, meeting in t. Divide each arc into four equal parts, and from their centres, through the points of division, draw the right lines I 3, I 4, I 5, I 6, I 7, and K 2, K 1, K 12, K 11; and they will meet the sides Kp, and I p, where the hours thereon must be placed, and these hour spaces in the arcs must be subdivided into half hours and quarters. Do the like for the other three angles, and draw the dotted lines, and set the hours in the insides where those lines meet them, as in the Figure; and the like hour lines will be parallel to each other in all the quadrants and in the angles.

Mark points for all these hours on the upper side, and cut out all the angular hollows, and the quadrantal ones, quite through the places where the four gnomons are to stand; and lay down the hours on their insides, as in Fig. 49, and then set in their four gnomons, which must be as broad as the dial is thick; and this breadth and thickness must be large enough to keep the shadows of the gnomons from ever falling quite out at the sides of the hollows, even when the sun's declination is at the greatest. Lastly, draw the equinoctial dial in the middle, all the hours of which are equidistant from each other, and the dial will be finished.

Babylonian and Italian Dials.

Babylonian and Italian dials.

92. The hours of these dials are not reckoned from noon, as with us, but on a Babylonian dial they are reckoned from sunrise to sunrise, and on an Italian dial from sunset to sunset. Thus, in Italy, the hour before sunset is the 23d hour of the day; and the second hour before sunset is the 22d hour, and so on. As the time of sunrise is continually varying, the beginning of the day (and consequently the time from noon at which any one of the hours shewn by these dials happens) is never the same on two succeeding days; the hours however are all equal. As both dials must be constructed on the same principles, it will be sufficient if we explain a particular case of one of them.

Fig. 15.

The hour is shewn by the shadow of the top of an upright stile, which is commonly the extremity of the axis of a common dial. Let us suppose that Fig. 15. represents a vertical south dial, on which it is proposed to trace the Babylonian hours; FC being the upright stile, and P the centre of the dial.

Find the hour next following sunrise, when the sun describes either tropic; for example, let it be four in summer, and eight in winter. Find next the sun's declination when he rises at these hours, and trace on the dial the hyperbolic curves $m\,m$, $n\,n$, which are the paths of the shadow when the sun has those declinations. Trace also the paths of the shadow when the sun describes the tropics: these last are only of use to terminate the hour lines when drawn on the dial.

Observe all the points where the hour lines of the dial cut the south parallel $m\,m$, then since the Babylonian hours proceed from 1 to 24, and in this parallel the sun rises at 8, therefore write 24 at that point of the parallel, where the 8 o'clock line passes, and write 1 at 9, 2 at 10, 3 at 11, &c.

Again, observe all the points where the hour lines of the dial cut the northern parallel $n\,n$; and since here the sun rises at 4, call that 24, at 5 write 1, at 6 write 2, at 7 write 3, at 8 write 4, at 9 write 5, at 11 write 7, at 12 write 8, and so on.

Next draw straight lines joining those points of $m\,m$, $n\,n$ the paths of the shadow which are marked with the same number, as 22, 33, 44, 55, and these are the Babylonian hour lines; that is, the shadow of the end of the stile will always be somewhere on the line 11, one hour after sunrise; it will be on the line 22, two hours after sunrise, and so on.

To understand the theory of this construction, we must consider that all the points of the sphere at which the sun is seen at sunrising, at different times of the year, are in the circumference of a great circle; and therefore its positions at one hour after sunrise, or at two hours after sunrise, &c. must also be in great circles. But with a little consideration it will appear that the extremities of the shadows projected by the gnomon, when the sun is at different points in a great circle, must all lie in a straight line, which will be the common section of that circle, and the plane of the dial; therefore the Babylonian hour lines must be straight lines, and two points in any one of them being known, the line itself is known; hence the truth of the construction is obvious.

As the hyperbolic lines $m\,m$, $n\,n$, are only of use in determining the hour lines, they need not appear on the dial.

Jewish Dial.

Jewish dial.

93. The *Jewish* hours, called the *naturals*, and also the *planetary* hours, begin at sunrise, and twelve are reckoned until sunset; hence they are all equal on the same day, but their length varies from day to day.

To delineate a dial of this kind, the paths of the shadow must be traced when the sun is in the tropics, and also in several intermediate points. The times of the day (reckoned according to the usual method) must be found at which the different Jewish hours happen, when the shadow describes each path; and the position of the shadow in its path must be found at the commencement of each Jewish hour. If curve lines be now traced through the same Jewish hour on all the hyperbolic paths, these curves will be the hour lines of the dial. The time is indicated by the shadow of the top of the stile, exactly as in the Babylonian dial.

The subject of dialling will be again adverted to, when we come to treat of the gnomonical projection of the sphere. See Projection of the Sphere. (ξ)

Diamond.

DIAMOND, the most beautiful and valuable mineral substance hitherto discovered. It is the most highly prized of the gems, and, by universal consent, is placed at the head of the mineral kingdom. Its colours are various. The most frequent tints are grey and white; less frequent are the blue, red, brown, yellow, and green, and the rarest of all the varieties of colour is the dark brownish black. It occurs in roundish grains or crystals; and of these latter, the most frequent form is the octahedron or double four-sided pyramid. Its fracture is distinctly foliated with a fourfold cleavage, and the folia of the cleavages are parallel with the planes of the octahedron. Its lustre is splendent and adamantine. It is seldom completely transparent; more generally it rather inclines to semitransparent, but the black variety is nearly opaque. It refracts single. It is the hardest mineral hitherto discovered, hence it scratches all other fossils; and its specific gravity varies from 3.488 to 3.600.

External characters.

Constituent parts.

In a history of gems, published by Boetius de Boot in the year 1607, it is conjectured that the diamond is an inflammable substance. In 1673, Boyle discovered, that, when exposed to a high temperature, part of it was dissipated in acrid vapours. In 1694 and 1695, experiments were made in the presence of the Grand Duke of Tuscany, which confirmed those of Mr Boyle, and shewed that the diamond, although the hardest of minerals, agrees with combustible bodies, in being combustible. In 1704, Sir Isaac Newton, in his great work on optics, hinted, that from its very great refractive power, it might be an unctuous substance coagulated. Newton does not appear to have been acquainted with the experiments made in Tuscany; and, besides, a considerable part of his work on optics was written in 1675. Since that period, the diamond has been often examined by chemists, and they find, that, when heated to the temperature of 14° of Wedgworth's pyrometer, or not so high as the melting point of silver, it gradually dissipates and burns; and combines with nearly the same quantity of oxygen, and forms the same proportion of carbonic acid as charcoal. Hence it consists principally of carbon.*

Physical characters.

When rubbed, whether rough or polished, it shews positive electricity; whereas quartz and the other precious stones, if rough, afford negative electricity, but when polished, positive electricity. It becomes phosphorescent when exposed to the rays of the sun. Many diamonds, however, do not become phosphorescent, although agreeing in colour, form, and transparency, with these which readily become luminous. The smaller acquire this property by a much shorter exposure to the light than the larger ones; sometimes a diamond that is not phosphorescent, by the mere action of the solar rays, may be made so, by previously immersing it for some time in melted borax. See Grossier in *Journ. de Physique*, vol. xx. p. 270.

Optical properties.

Since the time of Sir Isaac Newton, the diamond has been supposed to exceed every other body in its power of refracting and reflecting light, the index of refraction, according to that philosopher, being about 2.439. Dr Brewster, however, has found, that both Chromate of lead and Realgar exceed the diamond in their action upon light. Owing to the great quantity of light which it reflects at both surfaces, the diamond is never completely transparent; and in consequence of its high refractive power, it reflects all the light that is incident upon its posterior surface at an angle of incidence exceeding 24° 13′, from which cause it derives that high lustre to which it owes its value as an ornament. The diamond has always been considered as a crystal which gives single refraction; and in whatever way it is cut, it exhibits no direct marks of two images. Dr Brewster, however, has found, that it possesses the property of depolarising light; and it necessarily follows, from his theory of depolarisation, that, like many other bodies, it actually forms two images, which are polarised in an opposite manner, like those of all doubly refracting crystals; but in consequence of its possessing only one refractive power, these images can never be separated and rendered visible. The diamond polarises light by reflection at an angle of 68° 10′ according to experiment, and at an angle of 68° 2′ according to theory; and its dispersive power is 0.038, nearly the same as oil of olives, and very much below flint glass.

Geognostic situation.

In India, they are found, in general, in alluvial soil, and in the same situation in South America. According to Mawe, the diamonds of Brazil are found in a loose gravel immediately incumbent on the solid rock, and covered by vegetable mould, and recent alluvial matter. This gravel consists principally of rounded quartzy pebbles of various sizes, mixed with sand and oxide of iron, and containing blue, yellow, and white topazes, and grains of gold. In some parts of Serra do Frio, the gravel is cemented by means of iron into a hard conglomerate. Humboldt observed diamonds imbedded in amygdaloid, in specimens, in the collection belonging to the Stadtholder, now in Paris; also in similar specimens in England; and all of them were from India.†

Geographic situation.

The diamond was first found in Asia, where it is still collected, although not in such quantity as formerly. It occurs principally in the provinces of Golconda, Visapour, Bengal, and the island of Borneo.

In America, diamonds occur only in Brazil, in the district of Serra do Frio, where they were first discovered towards the beginning of the last century.

Method of searching for diamonds.

The usual method of searching for diamonds in Brazil, is to collect the disintegrated conglomerate, in which they are found, at the bottoms of rivers and of ravines, and by a laborious process of washing as long as the water comes off discoloured, to separate the mud from the distinct grains. The residue thus cleaned, is carefully examined for the diamonds which it may contain. These are distinguished partly by their crystalline form, but principally by their adamantine lustre. Diamonds of the smallest size, that is, whose weight does not exceed a fifth of a carat, or even the fifth of a grain, are by far the most abundant; these are of no use in jewellery, but when broken and ground to the requisite degree of fineness, form what is called *diamond powder*; a material used for cutting and polishing the diamond and other hard gems.

In some districts in India, diamonds are found loose in the narrow crevices of rocks: the miners make use of long iron rods, with hooks at the ends, and with these they draw out the loose contents of the fissures, and wash them in tubs, in order to discover the diamonds. In Colour, in Golconda, they dig in a large plain to the depth of ten or fourteen feet, and the earth is carried to the washing places by women and children.‡

* It was Sir George Mackenzie who first accurately determined the temperature at which diamond begins to burn. See Nicholson's *Journal*, vol. v. p. 104.

† Dr Thomson, in his *Annals of Philosophy*, mentions specimens of amygdaloid containing diamond, from India.

‡ At one period, nearly sixty thousand people were employed in searching for diamonds in Colour.

The celebrated traveller, Tavernier, who visited these mines, gives the following account of the process.

"After the miners have pitched upon the place where they intend to work, they level another place close by, of the same extent, or else a little bigger, which they enclose with a wall about two feet high; in the bottom of that little wall, at the distance of every two feet, they make small holes to let in the water, which they stop up afterwards, till they come to drain out the water again. This done, their labours are preceded by acts of devotion, and a very simple feast. When that is over, the men fall to digging, the women and children to carry the earth to the place prepared in that manner, as I have already described: they dig ten, twelve, and sometimes fourteen feet deep; but when they come to any water, they leave off. All the earth being carried into the place before mentioned, the men, women, and children, with pitchers, throw the water which is in the drain upon the earth, letting it soak for two or three days, according to the hardness of it, till it come to be a kind of batter, then they open the holes in the wall to let out the water, and throw on more water until all the mud is washed away, and nothing left but the sand; after that they dry it in the sun, and then they winnow the sand in little winnows as we winnow our corn. The small dust flies away, the great remains, which they pour out again upon the ground.

The earth being thus winnowed, they spread it with a kind of rake as thin as they possibly can, then with a wooden instrument like a pavier's rammer, about half a foot wide at the bottom, they pound the earth from one end to the other two or three times over; after that they winnow it again, and spreading it at one end of the van, for fear of losing any of the earth, they then look for the diamonds."

Diamonds are also collected from the gravel or sand of rivers. The river Gouel, near Soumelpour, in the province of Bengal, in the time of Tavernier, was said to be noted in this respect, and is the most ancient diamond district in the East. In the island of Borneo, diamonds are collected from the gravel and sand of the river Succadan.

Art of cutting and polishing diamonds.

The ancients were unacquainted with the art of cutting the diamond; and hence they used it in its natural, granular, or crystallised state. Even in the middle ages, this art remained still unknown; for the four large diamonds that ornament the clasp of the imperial mantle of Charlemagne, and which is still preserved in Paris, are uncut octahedral crystals.

The art of cutting and polishing diamonds was probably known to the artists of Hindostan and China at a very early period. European artists, until the fifteenth century, were of opinion that it was impossible to cut the diamond. Robert de Berghen, in the year 1456, endeavoured to polish two diamonds, by rubbing them against each other. He found, that, by this means, a facet was produced on the surface of the diamonds; and, in consequence of this hint, constructed a polishing wheel, on which, by means of diamond powder, he was enabled to cut and polish this substance in the same way as other gems are wrought by emery. This art has been gradually improved, particularly by the Dutch and British jewellers. For a long time all the finest diamonds were sent to Holland to be cut and polished, owing to the real or fancied superiority of the Dutch artists. Now the diamond cutters in London are considered as equal to any in the world; and we no longer hear of this gem being sent abroad to be cut by foreign artists, on account of any want of skill in our workmen.

The cutting and polishing of the diamond is effected in the following manner: If the rough diamond has rents or flaws which must be removed, or if the figure is such that it must be altered before it is regularly cut, we either split or saw off the part or parts. The splitting is effected by the blow of a hammer on a small chissel, placed in the direction of the folia or cleavage of the diamond. The sawing is effected by means of an iron wire attached to a bow; the wire is covered with diamond powder, and drawn backwards and forwords, until the portion is cut off. This, however, is a very tedious process, as the wire is generally cut through after having been drawn across the diamond five or six times, and thus requires very frequent renewal. When the diamond is in this way freed from its flaws, and reduced to the proper shape, it is next imbedded in a strong cement of brick dust and white pitch, fixed at the end of a spindle-shaped stick about a foot long, with that portion only projecting, the removal of which is to form the facet. The facet is formed by the friction of another diamond fixed in a stick in a similar manner to the former, with one of the angles projecting. In order to collect the powder and splinters that are detached during the process, the cutting is performed over a strong box, four or five inches square, furnished with a false bottom, perforated with excessively minute holes, in order to sift as it were the dust from the splinters; and also with two upright iron pegs fixed on the sides for the workmen to support and steady his fingers against, while, with a sharp repeated stroke, somewhat between scratching and cutting, he is wearing away the diamond on that part where the facet is to be made. This being done, the cement is softened by warming it, and the position of the diamond is changed, in order to bring a fresh part under the action of the cutting diamond. When, in this manner, all the facets have been cut upon the surface of the diamond, the cutting is completed. The next object is to polish the facets, and, at the same time, to remove any little inequalities that may have taken place in the cutting. The polishing mill is very simple. It consists of a circular horizontal plate of cast iron, 14 or 15 inches in diameter, (called a *skive*) suspended on a spindle, and put in motion by means of a wheel 5 or 6 feet in diameter, and turned by an assistant. From the centre to the circumference of the iron plate, are shallow grooves, formed by rubbing it in that direction with a fine grained sandstone; these grooves serve to retain the mixture of oil and diamond powder with which the plate is charged. In order to keep the diamond perfectly steady while the polishing of each facet is going on, the following contrivance is had recourse to. A copper cup, about three quarters of an inch in depth and width, and furnished with a stem about four inches long of thick copper wire, is filled with plumbers' solder, which also projects in a conical form beyond the rim of the cup; in the apex of this cone, the solder being softened by heat, the diamond is imbedded with one of the facets projecting. The stem of the cup is now put into very powerful pincers, which screw up with a nut and a wrench, and thus hold it perfectly tight. The handles of the pincers are of wood, are broad, and terminated by two feet about an inch high. In this position the diamond is placed on the plate, the pincers resting on their legs on the wood-

Diamond. en bench or table that supports the plate, and pressing at the same time against an upright iron peg; the broad part of the pincers between the legs and the diamond is then loaded with weights, both to steady the machine and to increase the pressure of the diamond against the skive. A little oil and diamond powder is now dropped on the plate; it is set in motion at the rate of about 200 revolutions in a minute, and the grinding and polishing processes now begin. The diamond is examined from time to time, and is adjusted so as to give the facet its true form. The heat occasioned by the friction is at all times considerable, and sometimes increases to such a degree as to soften the solder, and displace the diamond. This accident sometimes occasions a flaw in the diamond, and always damages the skive, by tearing up its surface. There is room in the skive for three or four diamonds, and a skilful operator can undertake the polishing of all of them at the same time. The completion of a single facet often occupies some hours.

Different forms into which they are cut.

Diamonds are cut and manufactured by jewellers into *brilliant, rose,* and *table* diamonds. To fashion a rough diamond into a brilliant, the first step is to modify the faces of the original octahedron, so that the plane formed by the junction of the two pyramids shall be an exact square, and the axis of the crystal precisely twice the length of one of the sides of the square. The octahedron being thus rectified, a section is to be made parallel to the common base, or girdle, so as to cut off $\frac{5}{18}$ths of the whole height from the upper pyramid, and $\frac{1}{18}$th from the lower. The superior and larger plane thus produced, is called the *table*, and the inferior and smaller one is named the *collet*; in this state it is called a *complete square table diamond.* To convert it into a brilliant, two triangular facets are placed on each side of the table, thus changing it from a square into an octagon; a lozenge-shaped facet is also placed at each of the four corners of the table, and another lozenge extending lengthwise along the whole of each side of the original square of the table, which, with two triangular facets, set on the base of each lozenge, complete the whole number of facets on the table side of the diamond, viz. eight lozenges, and twenty-four triangles. On the collet side are formed four irregular pentagons, alternating with as many irregular lozenges, radiating from the collet as a centre, and bordered by 16 triangular facets adjoining to the girdle. The brilliant being thus completed, is set with the table side upwards, and the collet side implanted in the cavity made to receive the diamond. Such is the method recommended by Mr Jeffries for cutting the brilliant diamond, and which ought to be attended to, if we are desirous that the diamond should display its highest degree of lustre and play of colour; but Mr Mawe remarks, "that so great a stress is laid by modern fashion on the superficial extent of a brilliant, that the rules just given are not much attended to; and, in forming the facets, artists trust principally to an accurate and well practised eye.*

The *regular rose diamond* is that form given to those stones, the spread of which is too great in proportion to their depth, to admit of being brilliant cut, without a great loss of substance. It is formed by inscribing a regular octagon in the centre of the table side of the stone, and bordering it by eight right angled triangles, the bases of which correspond with the sides of the octagon; beyond these is a chain of eight trapeziums, and another of sixteen triangles. The collet side also consists of a minute central octagon, from every angle of which proceeds a ray to the edge of the girdle, forming the whole surface into eight trapeziums, each of which is again subdivided by a salient angle (the apex of which touches the girdle,) into one irregular pentagon, and two triangles. † Diamond.

The *table diamond* is the least beautiful mode of cutting, and is used only for those stones, or rather fragments, which, with a considerable breadth, have only a very trifling depth.

Valuing diamonds.

In valuing diamonds, we have to attend to their *weight*, their *form* when cut, *colour, transparency, purity, or freedom from flaws, veins and stains*, the *regularity of the cleavage, proportion of the parts, and lastly, the setting on of the facets.*

1. Weight and form.

In the cutting either of a brilliant or a rose diamond, of regular proportions, so much is cut away, that the weight of the polished gem is not more than half that of the rough crystal out of which it was formed; whence the value of a cut diamond is esteemed equal to that of a similar rough diamond of twice its weight, exclusive of the cost of workmanship. The weight, and consequently the value, of diamonds, is estimated in *carats*, one of which is equal to four grains, and the difference between the price of one diamond and another, *cæteris paribus*, is as the square of the respective weights. Thus the value of three diamonds, of one, two, and three carats weight, is as one, four, and nine. The average price of rough diamonds, that are worth working, is about L. 2 for the first carat; and consequently in wrought diamonds, exclusive of the cost of workmanship, the cost of the first carat is L. 8. In other words, in order to ascertain the value of a wrought diamond, ascertain its weight in carats, and fractions of a carat, multiply this by two, then multiply this product into itself, and finally multiply this latter sum by L. 2. Hence a wrought diamond of

1	carat is worth	L.8
2	....	32
3	....	72
4	....	128
5	....	200
6	....	288
7	....	392
8	....	512
9	....	612
10	....	800
20	....	3,200
30	....	7,200
40	....	12,000
50	....	20,000
60	....	28,800
70	....	39,200
80	....	51,200
90	....	64,800
100	....	80,000

This rule, however, actually holds good only in the smaller diamonds of 20 carats and under; the larger ones, in consequence of the scarcity of purchasers, being disposed of at prices greatly inferior to their estimated worth. The value of some of the most perfect

* The brilliant form was invented in England.

† The finest rose cut diamonds were formerly manufactured in Holland. More than 300 years ago, this mode of cutting was known and practised at Antwerp.

Diamond. diamonds exceeds that given in the table; but for a stone that is flawed, cloudy, or of a bad colour, sometimes three quarters of the whole value may be deducted.

2. Colour. The most frequent colours of the diamond, as already mentioned, are the white and grey, and of these the most highly prized by the jeweller is the snow white. The brown varieties are of inferior value, and the yellow diamond, which is not uncommon, is only esteemed of equal value with the snow white variety when the colour is deep and pure. The other varieties of colour occur but rarely, and are viewed as objects of curiosity to the collector rather than as generally interesting to the jeweller. Thus a rose diamond is more valuable than a snow white diamond of equal weight, owing to the great beauty of its colour, and its rarity; the green diamond is much esteemed on account of its colour, but the blue diamond is only prized for its rarity, as the colour is seldom pure. The black diamond, which is uncommonly rare, and destitute of beauty, is very highly prized by collectors. *

3. Transparency. A good diamond must be nearly completely transparent. If semitransparent, it is of little value. Transparency and purity comprehend what is called the *water* of the diamond by jewellers. If the gem is transparent and quite pure, it is said to be of the first water; if less transparent and pure, of the second, or of the third water.

4. Freedom from flaws, veins, and stains. Diamonds in a state of nature are sometimes rent in different directions; these rents are either confined to the surface or central parts of the stone, or traverse its whole mass. When the rents traverse the whole mass of the stone, or traverse its interior, the value of the diamond is diminished one half. If the rents are superficial, the value of the stone is not very greatly diminished. It requires a very experienced eye to distinguish these different kinds of rents.

Rough diamonds are frequently *beamy*, that is, look fair to the eye, yet are so full of veins to the centre that no art or labour can polish them. Mr Milburn, in his valuable work on *Oriental Commerce*, vol. ii. p. 80, gives the following account of *beamy* diamonds. "The veins run through several parts of the stone, and sometimes through all; and when they appear on the outside, they shew themselves like protuberant excrescences, from whence run innumerable small veins, obliquely crossing one another, and shooting into the body of the stone. The stone itself will have a bright and shining coat, and the veins will look like very small veins of polished steel rising upon the surface of the stone. This sort of stone will bear no polishing, and is scarcely worth a rupee per mangalin. Sometimes the knot of the veins will be in the centre, the fibres will shoot outward, and the small ends terminate in the coat of the diamond. This is more difficult to discover, and must be examined by a nice eye; yet you may be able here and there to observe a small protuberance, like the point of a needle, lifting up a part of the coat of the stone; and though by a great deal of labour it should be polished, it will be a great charge, and scarcely pay for the cutting, and is therefore to be esteemed as little better than the former. But if you are not very careful, they will throw one of these stones into a parcel, and oftentimes the largest."

A good diamond should never contain small spots of a white or grey colour of a nebulous form; it should be free of small reddish and brownish grains, that sometimes occur on their surface, or in their interior.

5. Regularity of the cleavage. A good diamond should split readily in the direction of the cleavage; it sometimes happens, however, that the folia are curved, as is the case in twin crystals. When this is the case, the stone does not readily cut and polish, and is therefore of inferior value.

6. Proportion of parts. In the cut and polished gem, the thickness must always bear a certain proportion to the breadth. It must not be too thin nor too thick; when too thin it loses much of its fire, and appears not unlike glass.

7. The setting on of the facets. If these are not properly disposed, the diamond loses much of its fire, and its value is thereby diminished.

Diamond trade. The only diamond districts at present known, are those of India, Borneo, and Brazil. In the earlier ages, all the diamonds of commerce were obtained from India, but now the diamond mines of that country have become comparatively inconsiderable; several of them have been abandoned, and scarcely any of the rest contribute to the supply of the European market. Borneo furnishes annually a small quantity. The diamonds of the East are imported into Europe in their rough state, in small parcels, called *bulses*, neatly secured in linen, and sealed by the merchant, and are generally sold in Europe by the invoice, that is, are bought before they are opened, it being always found they contain the value for which they were sold in India, and the purchaser gives the importer such an advance on the invoice as the state of the market warrants. The bulse contains stones of various shapes and sizes. They may

* Mr Milburn has the following observations on the colour of rough diamonds, which are deserving the attention of the diamond merchant. "The colour should be perfectly crystalline, resembling a drop of clear spring water, in the middle of which you will perceive a strong light, playing with a great deal of spirit. If the coat be smooth and bright, with a little tincture of green in it, it is not the worse, and seldom proves bad; but if there is a mixture of yellow with green, then beware of it,—it is a soft greasy stone, and will prove bad.

If the stone has a rough coat, so that you can hardly see through it, and the coat be white and look as if it were rough by art, and clear of flaws or veins, and no blemish cast in the body of the stone (which may be discovered by holding it against the light,) the stone will prove good.

It often happens, that a stone will appear of a reddish hue on the outward coat, not unlike the colour of rusty iron; yet by looking through it against the light, you may observe the heart of the stone to be white, (and if there be any black spots or flaws, or veins in it, they may be discovered by a true eye, although the coat of the stone be the same,) and such stones are generally good and clear.

If a diamond appears of a greenish bright coat, resembling a piece of green glass, inclining to black, it generally proves hard, and seldom bad; such stones have been known to have been of the first water, and seldom worse than the second; but if any tincture of yellow seem to be mixed with it, you may depend upon its being a very bad stone.

All stones of a milky coat, whether the coat be bright or dull, if never so little inclining to a bluish cast, are naturally soft, and in danger of being flawed in the cutting; and though they should have the good fortune to escape, yet they will prove dead and milky, and turn to no account.

All diamonds of cinnamon colour are dubious; but if of a bright coat, mixed with a little green, then they are certainly bad, and are accounted amongst the worst of colours.

You will meet with a great many diamonds of a rough cinnamon coloured coat, opaque, ; this sort is generally very hard, and when cut, contains a great deal of life and spirit; but the colour is very uncertain; it is sometimes white, sometimes brown, and sometimes of a fine yellow."

be imported duty free, saving the duty granted to the East India Company on diamonds imported from any place within the limits of their charter.

Brazil affords more diamonds than India and Borneo, and it is said that nearly all the diamonds in the European market are obtained from that country. The diamond mines of Brazil belong either to the crown or to the Prince Regent. The trade in this gem, except through the medium of the government agents, is considered as contraband. Notwithstanding the severe penalties against this contraband trade, many diamonds are disposed of by private adventurers. The government diamonds, however, form the chief part of the trade. These are the produce of the different royal mines in the interior of Brazil; whence they are sent to the seat of government at Rio de Janeiro. The Prince Regent there selects from the whole such specimens as he chooses to add to his own magnificent collection, and the remainder are consigned to the Portuguese ambassador for the time resident in England, by whom they are deposited in the Bank for sale.

This branch of trade was, at one period, almost monopolized by the Dutch. The consul for Holland possessed an exclusive contract in Brazil for all the diamonds that were brought to the market in that country, whilst in India their agents were very active in securing all that were offered for sale. The trade is now divided between the English and Portuguese. The demand for diamonds of a moderate size is, at present, very great; and it would appear that the price of this gem has been gradually rising for several years. The sale of the larger diamonds has been very dull for many years past.

Uses.

The principal use of the diamond is in jewellery. It is also used by lapidaries for cutting and engraving upon harder gems, by watchmakers in their finer kinds of work; and by glaziers for cutting glass.

Account of some large diamonds.

We shall conclude our history of the diamond, with a short account of some of the largest diamonds hitherto discovered.

1. Authors mention a diamond weighing 1680 carats in the possession of the royal family of Portugal, which was found in Brazil, and is still uncut. This gem, if valued according to the rule already mentioned, should be worth L.5,644,800 sterling. It is now, however, generally believed, to be a fine white-coloured topaz.

2. The largest undoubted diamond, is that mentioned by Tavernier, which was in the possession of the Great Mogul, and which that traveller found to weigh $279\frac{9}{16}$ carats. It is the size of a hen's egg, of the same shape, and is cut in the rose form. Before cutting it weighed 900 carats. It was found in the mine of Colore, to the east of Golconda, about the year 1550.

3. The magnificent diamond on the top of the sceptre of the Emperor of Russia, deserves next to be noticed. It is perfectly pure; weighs 195 carats; and is the size of a pigeon's egg. It was one of the eyes of a Brahminical idol, and was stolen by a French grenadier, who disposed of it at a very low price; and lastly, after passing through three other hands, it was offered for sale to the Empress Catharine of Russia, who purchased it for about L.90,000 ready money, and an annuity of about L.4000 more.

4. The diamond of the late Grand Duke of Tuscany, now in Vienna, is of a pale lemon yellow colour, but beautifully formed, and weighs $139\frac{1}{2}$ carats.

5. The Pit or Regent diamond. It is cut in the brilliant form, and is said to be the most beautiful diamond hitherto found. It weighs $136\frac{1}{4}$ carats, and was purchased for L.130,000, although it is now valued at double that sum. It was brought from India by an English gentleman of the name of Pit, and was sold by him to the Regent Duke of Orleans, by whom it was placed among the crown jewels of France. It is now set in the handle of the sword of state of Bonaparte.

DIANA, in the ancient mythology, was the daughter of Jupiter and Latona, and the twin-sister of Apollo. Several characters are assigned to her by the classical writers; and she is clothed with various symbolical appendages, indicative of her different attributes: the goddess of the woods and of hunting upon earth; *Luna,* or the moon, in heaven; and *Hecate,* or the power presiding over witchcraft in the infernal regions.

The *Diana venatrix,* or goddess of the chace, is frequently represented in ancient sculpture; and she is described by the Roman poets, as running, with her vest shortened and girt up about her, yet flying back with the wind; she is tall of stature, and her countenance, though handsome, is somewhat masculine; her legs are naked, well-formed and strong; her feet are sometimes bare, and sometimes adorned with a species of buskin; she has often a quiver on her shoulder, and sometimes holds a javelin, but more commonly a bow, in her right hand.

When Diana is represented as presiding over the moon, she appears in a car drawn by stags or does, but more frequently by horses of a pure white colour, with a lunar crown or crescent upon her forehead. In this character she was invoked by women in childbed, under the appellation of *Juno Lucina,* or *Pronuba.*

The infernal Diana was distinguished by the name of *Hecate* or *Trivia*; in which character she was invoked in enchantments, and represented as a fury, holding instruments of terror in her hands, and grasping cords, swords, serpents, or burning torches. The appellation of *trivia,* or *triformis,* appears to have been derived from the custom of representing her sometimes with three bodies, or three heads.

Diana was known under several other names, most of which appear to have originated from the different places where she was worshipped; but she is easily distinguished in the figures which represent her, either by the crescent upon her head, or by her bow and arrows, or by her hunting dress, or by the dogs that accompany her. Among the Greeks, she was considered as the goddess of chastity, and hence virgins were given her for companions; yet she is represented, in the ancient fables, as by no means averse from gallantry; and is said to have bestowed her favours on Endymion, Pan, and Priapus. The Greeks appear to have derived their mythological system, in a great measure, from the Egyptians; and Diana, the sister of Apollo, is generally held to be the same with Isis, the sister of Osiris.

Diana had many oracles in ancient times; and many temples were dedicated to her worship. Of these latter, the most celebrated was that at Ephesus, which, on account of its size, structure, and embellishments, was esteemed one of the seven wonders of the world. Some account of the construction of this famous temple has been transmitted to us by two ancient authors, Vitruvius and Pliny. The former tells us, that it had eight columns in the fore-front, and as many in the back-front; that it had a double range of columns round it; and that it was of the Ionic order. Pliny states, (lib. xxxvi. cap. 14.) that two hundred and twenty years elapsed during its construction; that it was 425 feet in length, and 220 in breadth; that it was adorned with 100 columns, each 60 feet high, &c. Of these columns, 27 were very curiously carved, and the rest polished. The architect employed in executing this edifice was Ctesiphon, or Ctesifonte; and the bas-reliefs of one of the columns were done by Scopas, the most celebrated sculptor of antiquity. The altar was adorned with the masterly performances of the famous Praxiteles. The "great Diana of the Ephesians" was, according to Pliny, a small statue of ebony, made by one Canitia, though believed by the vulgar to have been sent down from heaven by Jupiter. The temple was several times destroyed and rebuilt, until it was finally burnt by the Goths, in the year 260.

It would appear from some reliques, that the worship of Diana had prevailed, in ancient times, both in Gaul and in Britain; and Mr Camden thinks it not improbable, that there was anciently a temple of Diana, where St Paul's Cathedral now stands, from the great number of ox heads which were found there in digging up the church-yard, in the reign of Edward I. An ancient MS. in the Cotton library informs us, that in the time of Melitus, the first bishop of London, Ethelbert, king of Kent, built a church in honour of St Paul, on the site where a temple of Diana previously stood; and certain ceremonies continued to be performed by the multitude, as far down as the days of Queen Elizabeth, on the day of St Paul's conversion, which obviously alluded to the worship of Diana. (*z*)

DIANDRIA. See BOTANY, p. 73, 75, and 85.

DIANELLA, a genus of plants of the class Hexandria, and order Monogynia. See Brown's *Prodromus Plant. Nov. Holl.* &c. p. 279, 280; and BOTANY, p. 194.

DIANTHUS, a genus of plants of the class Decandria, and order Digynia. See BOTANY, p. 216.

DIAPASON, in Music, an interval so called by the ancient writers, who supposed it to be full or complete, and contain all other intervals; its ratio is $\frac{1}{2}$, $= 612\Sigma + 12f + 53m$; the octave VIIIth, or *Major* EIGHTH, which see. (*ρ*)

DIAPASON DIAEX, the *greater,* an interval whose ratio is $\frac{3}{10} = 1063\Sigma + 21f + 92m$; the THIRTEENTH *Minor,* (or 13th,) which see.

DIAPASON DIAEX, the *lesser,* an interval whose ratio is $\frac{5}{16} = 1027\Sigma + 20f + 89m$; the THIRTEENTH *Major,* or XIII. which see.

DIAPASON DIAPENTE, an interval whose ratio is $\frac{1}{3}$, $= 970\Sigma + 19f + 84m$; the TWELFTH *Major,* (or XII.) which see. This interval was supposed by Mr Hoyle to be equal to nine tones and a semitone; and by M. Capella, to be equal to eight tones and a semitone, the fallacy of which will, however, appear from the following equations, in the characters used in Plate XXX. Vol. II. viz. $XII + 2\Sigma = 9T + \mathcal{S}$, $XII + 2\Sigma = 8T + t + \mathbb{S}$, $XII + \Sigma = 7T + 2t + S$, and $XII + \Sigma = 6T + 3t + \mathbb{S}$. The same writer also maintained this interval, the XII. to be equal to 19 semitones, and 38 diesis. See DIESIS *greater,* of M. Capella.

DIAPASON DIATESSERON, an interval whose ratio is $\frac{3}{8} = 866\Sigma + 17f + 75m$; the ELEVENTH *Minor,* (or 11th,) which see. M. Capella supposed this interval to be equal to eight tones and a semitone, but which is not correctly so, for $11\text{th} + 2\Sigma = 8T + \mathcal{S}$, $11\text{th} + 2\Sigma = 7T + t + \mathbb{S}$, $11\text{th} + \Sigma = 6T + 2t + S$, and $11\text{th} + \Sigma = 5T + 3t + \mathbb{S}$. M. Capella also says, that the 11th is equal to 17 semitones and 34 dieses. See DIESES *lesser*, of M. Capella.

DIAPASON DITONE, an interval whose ratio is $\frac{2}{5}$, $= 890\Sigma + 16f + 70m$; the TENTH *Major*, (or Xth,) which see.

DIAPASON IMPERFECT, an interval whose ratio is $\frac{25}{48}$, $= 576\Sigma + 11f + 50m$; the EIGHTH *Acute Minor*, (or 8th of Liston,) which see.

DIAPASON, SEMIDITONE, an interval whose ratio is $\frac{5}{12}$, $= 773\Sigma + 15f + 67m$; the TENTH *Minor*, (or 10th,) which see.

DIAPASON, SUPERFLUOUS, an interval whose ratio is $\frac{12}{25}$, $= 648\Sigma + 13f + 56m$; the EIGHTH *Superfluous*, which see.

DIAPASON STOPS, in Music, are ranges of pipes through the scale of an organ, which are considered as the standard of pitch, and are usually first tuned; after the pitch of C, in the middle octave, answering to the tenor cliff or ledger-line above the bass or below the treble staves, has been adjusted, by means of a standard pipe, or by some of the methods described under our article CONCERT *Pitch*. The diapasons are of two kinds; the *open* diapason stop, which is a range of cylindrical pewter pipes, some of which are commonly gilt, and exhibited in the front of the instrument; and the *stopt* diapason stop, a range of square wooden pipes, with plugs or stoppers in their upper ends, which are drawn out or shoved in, to effect the tuning. In order to yield the same notes, these stopt wooden pipes are only about half the length or height of the open metal ones. See ORGAN. (ρ)

DIAPENSIA, a genus of plants of the class Pentandria, and order Monogynia. See BOTANY, p. 140.

DIAPENTE, in Music, or *Pentachord*, is an interval whose ratio is $\frac{2}{3}$, $= 358\Sigma + 7f + 31m$; the FIFTH *Major*, (or Vth,) which see. (ρ)

DIAPHANOMETER, from διαφανεια, *transparency*, and μετρον, a *measure*, is the name of an instrument invented by Saussure, for measuring the transparency of a portion of the atmosphere.

The Cyanometer, which we have already described under its proper head, by ascertaining the intensity of the blue colour of the sky, enables us to measure the total effect of the vapour and evaporation diffused through the whole depth of the atmosphere; whereas the Diaphanometer, by measuring the transparency of a portion of the atmosphere of limited extent, is intended to shew the quantity of vapour or evaporation existing in that portion.

The distances at which the same object ceases to be visible in different states of the atmosphere, are obviously relative measures of the transparencies of the portion of the atmosphere, between the object and the observer, at the times when the observations were made; and hence it was Saussure's first difficulty to find objects, the disappearance of which could, at a certain distance, be ascertained with the utmost accuracy. He found that the extent of disappearance could be more accurately perceived when a black object was placed upon a white ground, than when a white object was placed upon a black ground; that the results were still more precise, when the disappearance was observed in sunshine, than when it was observed in the shade; and that they were still more correct, when the white shade, surrounding a black circle, was itself encircled by a ground of a darker hue.

The following account of Saussure's experiments, by Dr F. W. Murhard, of Gottingen, is so short and perspicuous, that it will not admit of abridgment.

Saussure's Diaphanometer.

"If a circle totally black, of about two lines in diameter, be fastened on the middle of a large sheet of paper or pasteboard, and if this paper or pasteboard be placed in such a manner as to be exposed fully to the light or the sun, if you then approach it at the distance of three or four feet, and afterwards gradually recede from it, keeping your eye constantly directed towards the black circle, it will appear always to decrease in size the farther you retire from it, and at the distance of 33 or 34 feet will have the appearance of a point. If you continue still to recede, you will see it again enlarge itself; and it will seem to form a kind of cloud, the darkness of which decreases more and more, according as the circumference becomes enlarged. The cloud will appear still to increase in size, the farther you remove from it; but at length it will totally disappear. The moment of the disappearance, however, cannot be accurately ascertained; and the more experiments were repeated, the more were the results different. This is an observation perfectly accurate; and having myself made a series of experiments under like circumstances, I am the more convinced of the truth of it.

M. de Saussure having reflected for a long time on the means of remedying this inconveniency, saw clearly, that, as long as this cloud took place, no accuracy could be obtained; and he discovered that it appeared in consequence of the contrast formed by the white parts, which were at the greatest distance from the black circle. He thence concluded, that if the ground was left white near this circle, and the parts of the pasteboard at the greatest distance from it were covered with a dark colour, the cloud would no longer be visible, or at least would almost totally disappear.

This conjecture was confirmed by experiment. M. de Saussure left a white space round the black circle, equal in breadth to its diameter, by placing a circle of black paper, a line in diameter, on the middle of a white circle three lines in diameter, so that the black circle was only surrounded by a white ring, a line in breadth. The whole was pasted upon a green ground. A green colour was chosen, because it was dark enough to make the cloud disappear, and the easiest to be procured.

The black circle, surrounded in this manner, with white on a green ground, disappeared at a much less distance, than when it was on a white ground of a large size.

If a perfectly black circle, a line in diameter, be pasted on the middle of a white ground exposed to the open light, I can observe it at the distance of from 44 to 45 feet; but if this circle be surrounded by a white ring, a line in breadth, while the rest of the ground is green, I lose sight of it at the distance of only $15\frac{1}{2}$ feet.

According to these principles, M. de Saussure delineated several black circles, the diameters of which increased in a geometrical progression, the exponent of which was $\frac{3}{2}$. His smallest circle was $\frac{1}{5}$ or 0.2 of a line in diameter; the second, 0.3; the third, 0.45; and so on to the sixteenth, which was 87.527, or about 7 inches $3\frac{1}{2}$ lines. Each of these circles was surrounded by a white ring, the breadth of which was equal to the diameter of the circle, and the whole was pasted on a green ground.

Diaphanometer.

M. de Saussure selected, for his experiments, a straight road or plain of about 12 or 1500 feet in circumference, which towards the north was bounded by trees or an ascent. Those who repeat them, however, must pay attention to the following remarks:—When a person retires backwards, keeping his eye constantly fixed on the pasteboard, the eye becomes fatigued, and soon ceases to perceive the circle; as soon, therefore, as it ceases to be distinguishable, you must suffer your eyes to rest; not, however, by shutting them, for they would when again opened be dazzled by the light, but by turning them gradually to some less illuminated object in the horizon. When you have done this for about half a minute, and again directed your eyes to the pasteboard, the circle will be again visible, and you must continue to recede till it disappear once more. You must then let your eyes rest a second time, in order to look at the circle again, and continue in this manner till the circle becomes actually invisible.

If you wish to find an accurate expression for the want of transparency, you must employ a number of circles, the diameters of which increase according to a certain progression; and a comparison of the distances at which they disappear, will give the law according to which the transparency of the atmosphere decreases at different distances. If you wish to compare the transparency of the atmosphere on two days, or in two different places, two circles will be sufficient for the experiment.

According to these principles, M. de Saussure caused to be prepared a piece of white linen cloth eight feet square. In the middle of this square he sewed a perfect circle, two feet in diameter, of beautiful black wool: Around this circle he left a white ring two feet in breadth, and the rest of the square was covered with pale green. In the like manner, and of the same materials, he prepared another square; which was, however, equal to only $\frac{1}{12}$ of the size of the former, so that each side of it was 8 inches; the black circle in the middle was 2 inches in diameter, and the white space around the circle was 2 inches also.

If two squares of this kind be suspended vertically and parallel to each other, so that they may be both illuminated in an equal degree by the sun, and if the atmosphere, at the moment when the experiment is made, be perfectly transparent, the circle of the large square, which is twelve times the size of the other, must be seen at twelve times the distance. In M. de Saussure's experiments, the small circle disappeared at the distance of 314 feet, and the larger one at the distance of 3588 feet, whereas it should have disappeared at the distance of 3768. The atmosphere, therefore, was not perfectly transparent. This arose from the thin vapours which at that time were floating in it."

New diaphanometers suggested.

The writer of this article, several years ago, made numerous experiments both with the diaphanometer of Saussure, and with other contrivances, but they were not attended with any very satisfactory results. One of the instruments which he employed, was a telescope with a variable magnifying power, produced by the motion of a second object-glass along the axis of the instrument. By this means, he got rid of the error arising from the adjustment of the eye to different distances; and that organ did not need the successive refreshments which Saussure found it to require. The magnifying power being known with the greatest accuracy from a scale on the moveable tubes, we had only to shift the moveable object-glass till the object vanished, and the magnifying power, indicated by the scale, became a relative measure of the transparency of the atmosphere. By this means we are enabled to extend our experiments to a much larger portion of atmosphere.

Diaphragm ‖ Diarbekr.

Another contrivance which we adopted, was a telescope having tubes twice the length of what was necessary for ordinary purposes, in order to allow the eye-piece to be pulled out a great way beyond the focal point of the object-glass, and to be pushed as far within it. When the telescope was adjusted to distinct vision, the object was seen with perfect clearness; but when indistinct vision was produced by pushing in or pulling out the eye-piece, the object of course vanished, and the distance of the eye-piece from the focal position, was obviously a measure of the transparency of the atmosphere. For farther information on this and analogous subjects, see *Mem. Acad. Turin.* vol. iv. where Saussure first published an account of his invention; Gren's *Neue Journal der Physik*, vol. iv. which contains Murhard's Paper; Tilloch's *Phil. Magazine*, vol. iii. p. 377; Bouguer's *Traité d'Optique sur la gradation de la Lumiere*, livre iii. 1760; and Lambert's *Photometria*, the last of which we have not seen, but it is referred to by Murhard. (π)

DIAPHRAGM. See Anatomy.

DIARBEKR, or Diarbek, from *Dhyar* a duke, and *bekr* a country, is the name of one of the pashaliks of the province of Armenia and the Ottoman empire. This pashalik, which, next to that of Erzeroon, is one of the largest in Armenia, is situated between the Tigris and the Euphrates, and is separated from the dependencies of Merdin by a small river, and by a branch of Mount Masius. The whole of the pashalik is difficult of access, from the number of mountains which it contains. It is interspersed with narrow and fertile valleys, and abounds in the most beautiful and romantic scenery. Diarbekr was formerly the name of an extensive province, which is now divided into different pashaliks. See Macdonald Kinneir's *Geographical Memoirs of the Persian Empire*. (π)

DIARBEKR, or Kara-Amid, the capital of the pashalik of the same name, and the *Amida* of the ancients. It is situated in a delightful plain or rather table land, at the vertex of a triangle formed by one of the inflexions of the Tigris, which encompasses it on the east. It is encircled with a prodigious wall, flanked with seventy-two towers. This wall is built of black stone, from which circumstance the city derived the name of *Kara-amid*, or the Black Amid. This wall, which is now in a ruinous condition, is described by Mr Kinneir as far superior, both in height and solidity, to any thing which he had seen either in Europe or Asia. He thinks that there is no doubt of its having been built by the Romans, and attributes the mistake of those travellers, who ascribe it to the Arabs, to the number of Kufic inscriptions which have been inserted into different parts of the walls and towers at a later period. The stile of architecture has no resemblance to that of the Arabs, and similar Arabic inscriptions are often found in the ruins of Persepolis, the castle of Shuster, and the Rock of Besitoon. The houses, which are built of stone, have a respectable appearance, but the streets, though well paved, are narrow and dirty. In this city there are two or three stately piazzas, well stored with corn and provisions, and all kinds of merchandise; and there is a large magnificent mosque, which was formerly a church belonging to the Christians. The castle, which is on the north side of the town, is encompassed with a strong wall. It has many courts and elegant buildings, in which the Pacha and his officers reside. The river Tigris, which in spring rises to a great height, is crossed by a bridge of twelve arches, situated about half a mile below the town. Mr Kinneir describes Diarbekr as having a grand appearance when viewed from a distance. "The elevation of the surrounding mountains," says he, "the windings of the Tigris, and height of the walls and towers, with the cupolas of the mosques, give it an air of grandeur, far above that of any other city which I have visited in this quarter of the world." The inhabitants manufacture cotton, silk, copper, and iron, and export it to Bagdad and Constantinople; but they are principally employed in dressing, tanning, and dyeing goat skins, commonly called Turkey leather. Great numbers of pilgrims frequent this city, and at some distance from the town there is a large village with a caravansera, where the caravans that go to or from Persia, find a cheaper accommodation than in the caravanseras within the town.

Diarbekr is said to have been founded by Taimuras. The Emperor Constans strengthened it with fortifications, and it was then regarded as the strongest place in Mesopotamia. In A. D. 359, however, it was taken by Sapor D'Ulaktaf, and in 505 by Cobades his descendant. The Arabs, the Silguckians, and the Attabeks, had it successively in their possession. It was pillaged in 1393 by Timour, became an independent state under the princes of the Black Ram, and was at last taken by Selim the First, from Shah Ismael Sefi.

The population of Diarbekr is reckoned at 30,000 souls, the greater part of whom are Turks, and the rest Armenians, Curds, Jacobites, and Catholics. The men are affable and courteous, and the women enjoy a great degree of liberty, and live in terms of intimacy with the Christian women. Distance from Merdin 60 miles; from Orfa 287; and from Malatea 172½. The position of this city as ascertained by Mr Simon, is in East Long. 39° 52′, and North Lat. 37° 55′ 30″. See Macdonald Kinneir's *Geographical Memoir of the Persian Empire*, p. 332—335. (π)

DIARRHŒA. See MEDICINE.

DIASCHISMA, in Music, (ℰ) an interval so named by Pythorus, the remainder when a limma is taken from an apotome. By some it is called the ancient comma, and the comma syntonum. It was the comma maximum of Boethius; the comma ditonicum of Kollman, and his major comma; the quint wolf of Earl Stanhope. It has also been called the tonemajor wolf, and is the *least sum* of the quint temperaments and wolves in a douzeave.

The ratio of the diaschisma is $\frac{524,288}{531,441}$; the component primes of which are $\frac{2^{19}}{3^{12}}$; its common logarithm is .9941148,6098, and its reciprocal .0058851,3902; in the Binary logarithms of Euler, or decimals of the octave, it is =.019550; in major comma logarithms, 1.0908429; in schismas, 12.007862405; in Farey's Notation, which we have chosen as a common scale or measure of intervals, it is = 12Σ + m. In tunable intervals, it is 5V—7 4ths, and may be correctly obtained on an organ, by tuning upwards five perfect major fifths, and downwards seven perfect minor fourths, either successively or alternately, as is most convenient, when the last sound will stand in relation to the first, as diaschisma. None of the 59 notes on Mr Liston's enharmonic organ are thus related to each other, although 13 intervals between adjacent notes thereon, differ from it only one schisma, and 26 others only two schismas, respectively. See *Philosophical Magazine*, vol. xxxix. p. 419.

The following equations, in terms of the several intervals, in Plate XXX. Vol. II. exhibit the relation of the diaschisma to each of the 30 intervals less than the least concord, respectively, and to several of the conchords, viz.

đ = Σ + c
= 2Σ + €
= 12Σ + m

đ = P — L	đ = 3c — ℰ	đ = 5T — 2 4ths
= π — χ	= 4c — ʃ	= 6T — VIII

= ℰ — R — χ		
= 𝒻 — c — r		

$\frac{t}{u}$đ be any small fraction of the diaschisma, or power of its numeral ratio, whose index is $\frac{t}{u}$; then will $\frac{1055729 \times u - 7153 \times t}{1055729 \times u + 7153 \times t}$ be equal to its numeral ratio extremely near.

If, for example, $\frac{t}{u} = \frac{1}{2}$, the theorem gives us $\frac{2104305}{2118611}$ as the approximate ratio of the half diaschisma or schisma of Galileo and Glareanus; and its logarithm will be found to differ only 1 in the eighth place of decimals from the true log. of ½đ. This interval is = 5.996068Σ + m, or 6 + Σ½m, and is = 2½T—4th. (ȝ)

DIASCHISMA OF BOETHIUS, is an interval, described as the half the limma, or ½L, which has by some writers also been called the Half Diesis, or Minor Semitone. Its approximate ratio is $\frac{585}{601\frac{1}{2}}$, found by a general theorem $\frac{(N+D)u-(D-N)t}{(N+D)u+(D-N)t}$, wherein N and D denotes the numerator and denominator of a small fraction, ($\frac{243}{256}$ in this case), whose $\frac{t}{u}$ power is to be sought in another vulgar fraction; the above ratio being true within less than the smallest known interval, or *m*. Its value, in Farey's notation, is $22.9251695\Sigma + f + 2m$, or $23\Sigma + \frac{1}{2}f + 2m$; its common log. $=$ .9886813,5414.

DIASCHISMA of Dr BUSBY, is an interval, the half of the minor semitone, or $\frac{1}{2}\mathcal{S}$; whose approximate ratio, found as above, is $\frac{97}{99}$, which differs only about $\frac{1}{4}$ m from the true interval. It is $=18.0708993\Sigma + 2m$, or $18\Sigma + \frac{1}{2}f + 1\frac{1}{2}m$. and its log. .9911356,1652.

DIASCHISMA of EULER, is an interval whose ratio is $\frac{2025}{2048}$, $= 10\Sigma m$, or the COMMA MINOR, which see.

DIASCHISMA of S. ROOTSEY, is an interval not diatonic, but intended as an approximation to the true đ mentioned above, whose ratio he states to be $\frac{73}{74}$, $= 12.0483985\,\Sigma + m$; its common log. being .9940911,4039.

DIASCHISMA TRIPLE, is a compound or multiple interval, which is mentioned here, from its resulting also, as simple or prime intervals usually do, from the subtraction of simple intervals, viz. $3đ = \mathcal{S} - f$, $= L - \varphi$, $= S + 4\Sigma - \mathcal{f}$, $= P + 4\Sigma - \partial$, $= \mathfrak{S} - c - f$, $= S - \mathcal{E} - f$, &c. Its ratio is $\frac{2^{57}}{3^{36}}$ which is expressed in large numbers, of which the first figures are $\frac{144111, \&c.}{150094, \&c.} = 35.850339\,\Sigma + f + 3m$, or $36\Sigma + 3m$. Its log. is .9823445,8294.

DIASPASIS, a genus of plants of the class Pentandria, and order Monogynia. See R. Brown's *Prodrom. Plant. Nov. Holl. et Ins. Van Diemen.* p. 586, and BOTANY, p. 175.

DIATESSARON, in Music, is an interval, sometimes called a tetrachord, whose ratio is $\frac{3}{4}$, $= 254\Sigma + 5f + 22m$, or the FOURTH *Minor*, which see.

DIATESSARON of HOLDER, an interval, improperly so called, whose ratio is $\frac{3}{16}$, $= 1478\,\Sigma + 29f + 128m$, or the EIGHTEENTH *Minor*, which see.

DIATONIC ELEMENTS, in Music, are the *Major* TONE (T), the *Minor* TONE (t), and the *Major* SEMITONE (S). By the combination of which three intervals, all others which occur in the music now in use, called the diatonic, may be derived. Intervals thus expressed, as Mr Liston has done throughout his valuable "Essay on Perfect Intonation," are said to be expressed in, or computed by a notation of diatonic elements; but Mr Liston follows Dr Robert Smith, in denominating the lesser interval a Hemitone, and marking it H, instead of S, which is used in our Table, Plate XXX. Vol. II. and in our several musical articles.

Mr Maxwell, in his "Essay upon Tune," calculates by these elements; but he calls them by the names Greater Tone, Lesser Tone, and Semitone, and marks them G, L, and S, instead of T, t, and S, as we do. Owing to the constant occurrence of negative signs, in the minuter parts of the calculations, unless that an octave, or $3G + 2L + 2S$, is added to every interval, as Mr Maxwell sometimes does to avoid them; and owing also to the want of any *apparent value* in the three terms *collectively*, this notation often fails to convey readily a most important piece of information, viz. which of two intervals, expressed in it, are the largest? As, for instance, whether is the c or ✕B, of Maxwell, p. 194, the most acute, or the largest intervals above the bass C? the former being 3 2 2, and the latter 4 2 0 in his Table, or the c and B'✕ of Liston, which are expressed by the same numbers: whereas, had Farey's notation been used, and these two notes been expressed by $612\Sigma + 12f + 53m$, and $602\Sigma + 12f + 52m$, it would at once have appeared that the former is the largest, and that the difference of them is $10\Sigma + m$, instead of the ambiguous difference $2S - G$, as Maxwell has it.

For all purposes of perfect harmony, or diatonic calculations, his *artificial commas*, or the first or largest only of his elements, Σ, might be used, as shewn in the Philosophical Magazine, vol. xxxix. p. 419, and by which the whole of the calculations, necessary for understanding and proving Mr Liston's system of perfect harmony, is reduced to the adding or subtracting of numbers, which rarely exceed three figures, and which surely need not deter any practical musician from the attempt, however slight his knowledge of arithmetic.

By some, the prime digits, 2, 3, and 5, have also been called Diatonic elements, because they are, in every instance, composed of these numbers, and no other prime digits, except 1, which does not affect ratios, or the multiplications or divisions by which they are compounded. See MUSICAL *Primes*. (ε)

DIATONICUM, DIATONUM, in the music of the Greeks, was distinguished among their *genera*, according to Euclid, Eratosthenes, Ptolemy, &c. by a tetrachord, ascending according to the following numerical ratios, viz. $\frac{243}{256} \times \frac{8}{9} \times \frac{8}{9} = \frac{3}{4}$, which, in our notation, (see Plate XXX. Vol. II.) is as follows, viz.

$$\begin{aligned} T &= 104\Sigma + 2f + 9m \\ T &= 104\Sigma + 2f + 9m \\ L &= 46\Sigma + f + 4m \\ \hline 4th &= 254\Sigma + 5f + 22m \end{aligned}$$

DIATONICUM EQUABILE, was a genus of Ptolemy, which, according to Dr Wallis, was thus composed, viz. $\frac{11}{12} \times \frac{10}{11} \times \frac{9}{10} = \frac{3}{4}$, whence we have,

$$\begin{aligned} \tfrac{9}{10} &= 93.000000\,\Sigma + 2f + 8m \\ \tfrac{10}{11} &= 84.401367\,\Sigma + 2f + 7m \\ \tfrac{11}{12} &= 76.598633\,\Sigma + f + 7m \\ \hline 4th &= 254.000000\,\Sigma + 5f + 22m \end{aligned}$$

DIATONICUM INTENSUM, or *Syntonum*, this most important of the Greek genera, according to Didymus, Euclid, and many other writers, had a tetrachord thus composed, viz. $\frac{15}{16} \times \frac{9}{10} \times \frac{8}{9} = \frac{3}{4}$, or, in our notation,

$$\begin{aligned} T &= 104\Sigma + 2f + 9m \\ t &= 93\Sigma + 2f + 8m \\ S &= 57\Sigma + f + 5m \\ \hline 4th &= 254\Sigma + 5f + 22m \end{aligned}$$

Or, accordi g to Ptolemy, thus,

$$\begin{aligned} t &= 93\Sigma + 2f + 8m \\ T &= 104\Sigma + 2f + 9m \\ S &= 57\Sigma + f + 5m \\ \hline 4th &= 254\Sigma + 5f + 22m \end{aligned}$$

Of all the numerous scales of musical intervals which the Greek musicians used, or their own or subsequent theoretical writers have pretended that they did, the two last only, called the Diatonic, (see DIATONIC *Elements*,) are now in use, since our chromatic scales differ essentially in their construction and use, especially on tempered instruments, from any that are found in the ancient musical writers.

According to Aristoxenus, in this genus the tetrachord was divided into 30 equal parts, and was thus composed, viz. $6+12+12=30$, or,

$$\frac{12}{30}\text{ths or } \frac{2}{5}\times 4\text{th}=101.598428\Sigma+2f+9m$$
$$\frac{12}{30}\text{ths or } \frac{2}{5}\times 4\text{th}=101.598427\Sigma+2f+9m$$
$$\frac{6}{30}\text{ths or } \frac{1}{5}\times 4\text{th}=\ \ 50.803145\Sigma+f+4m$$
$$4\text{th}=254.000000\Sigma+5f+22m$$

According to Archytas, Dr Wallis, &c. it was thus divided, viz. $\frac{27}{28}\times\frac{8}{9}\times\frac{7}{8}=\frac{3}{4}$, which in our notation is,

$$\frac{7}{8}=117.947096\Sigma+2f+10m$$
$$\frac{8}{9}=104.000000\Sigma+2f+9m$$
$$\frac{27}{28}=\ \ 32.052904\Sigma+f+3m$$
$$4\text{th}.=254.000000\Sigma+5f+22m$$

DIATONICUM MOLLE, or soft diatonic. This genus, according to Euclid, ascended by a hemitone or half major tone, an incomposite or spiss interval, and a trihemitone, composed of five quadrantal dieses or quarters of a major tone, making up the tetrachord, which, in our notation, will stand thus, viz.

$$\frac{5}{4}T=129.927135\Sigma+3f+11m$$
$$72.076796\Sigma+f+6m$$
$$\frac{1}{2}T=\ \ 51.996069\Sigma+f+5m$$
$$4\text{th}=254.000000\Sigma+5f+22m$$

The incomposite of this system was, it is said, by Dr Holder, accounted to be three quadrantal dieses, or $\frac{3}{4}T = 78.072865\Sigma+f+7m$, but which exceeds it by $5.996069\Sigma+m$, being $\frac{1}{2}d$, or the schisma of Galileo and Glareanus, which differences, as in the genus CHROMATICUM MOLLE, &c. (which see) is occasioned by the ancients having assumed, that two and a half major tones were equal to a fourth instead of $2\frac{1}{2}T=4\text{th}+\frac{1}{2}d$, as the fact is.

According to Aristoxenus, the tetrachord was here divided into 30 equal parts, of which the same was composed as follows, viz. $6+9+15=30$, or,

$$\frac{15}{30}\text{ths or } \frac{1}{2}\times 4\text{th}=126.9251695\Sigma+3f+11m$$
$$\frac{9}{30}\text{ths or } \frac{3}{10}\times 4\text{th}=\ \ 76.2716855\Sigma+f+7m$$
$$\frac{6}{30}\text{ths or } \frac{1}{5}\times 4\text{th}=\ \ 50.8031450\Sigma+f+4m$$
$$4\text{th}=254.0000000\Sigma+5f+22m$$

According to Ptolemy, it was, however, constituted thus, viz. $\frac{20}{21}\times\frac{9}{10}\times\frac{7}{8}=\frac{3}{4}$, or

$$\frac{7}{8}=117.947096\Sigma+2f+10m$$
$$\frac{9}{10}=\ \ 93.000000\Sigma+2f+8m$$
$$\frac{20}{21}=\ \ 43.052904\Sigma+f+4m$$
$$4\text{th}=254.000000\Sigma+5f+22m$$

And Dr Pepusch and Mr Overend are of opinion that this genus was as follows, viz,

$$T+E=125\Sigma+2f+11m$$
$$2S=\ \ 72\Sigma+2f+6m$$
$$S=\ \ 57\Sigma+f+5m$$
$$4\text{th}=254\Sigma+5f+22m$$

DIATONICUM TONICUM, was a genus of Ptolemy, which, according to Dr Wallis, was thus constituted, viz. $\frac{27}{28}\times\frac{7}{8}\times\frac{8}{9}=\frac{3}{4}$, which, in our notation, is as follows,

$$\frac{8}{9}=104.000000\Sigma+2f+9m$$
$$\frac{7}{8}=117.947096\Sigma+2f+10m$$
$$\frac{27}{28}=\ \ 32.052904\Sigma+f+3m$$
$$4\text{th}=254.000000\Sigma+5f+22m$$

This differs from one of the preceding genera, only by the arrangement of the intervals.

DIATONUM, in Music, according to Mr Henfling, is an interval whose ratio is $\frac{15}{16}$, $=57\Sigma+f+5m$, or the SEMITONE *Major*, which see.

DIAZEUTIC TONE, in Music, an interval whose ratio is $\frac{8}{9}$, $=104\Sigma+2f+9m$, or the TONE *Major*. See that article. (ε)

DICTATOR. See ROME.

DIDELTA, a genus of plants of the class Syngenesia, and order Polygamia Trustanea. See BOTANY, p. 307.

DIDEROT, DENYS, a French author of considerable celebrity, was the son of a master-cutler at Langres, where he was born in the year 1713. He derived his elementary instruction from the Jesuits, who, finding him to be a youth of promising talents, were desirous of retaining him in their society; but he evinced no inclination for the ecclesiastical life, and his father, therefore, sent him to Paris to finish his studies, intending that he should follow the profession of the law. Diderot, however, exhibited an early partiality for literary pursuits, to which he addicted himself in a degree that was incompatible with the duties of his situation. His father having taken offence at his conduct, refused, for some time, to continue his support. But young Diderot, undismayed by difficulties, continued to prosecute his studies in physics, geometry, and metaphysics, in which, and in the *belles lettres*, he made considerable progress. He commenced his career as an author about the age of thirty; and one of the earliest of his publications was a translation of Stanyan's History of Greece from the English. In 1745, he published a small work, entitled *Principles of Moral Philosophy*; and in the following spring appeared his *Pensées Philosophiques*, which procured him considerable reputation. From this period he was regarded as a disciple of the new philosophy, of which he afterwards became one of the most able and indefatigable advocates. He republished his *Pensées* under the title of *Etrennes aux esprits forts*, when they obtained a very general circulation, and contributed greatly to the dissemination of those philosophical opinions which were for a long time so prevalent in France.

About this period, Diderot, in concert with D'Alembert, laid the foundation of the famous *Dictionnaire Encyclopedique*; a work which formed a sort of epoch in the annals of science, and which appears to have been intended to serve, not only as a magazine of all human knowledge, but as an engine to subvert all established opinions. The first edition of this work was published between the years 1751 and 1767, in 28 volumes, folio. The reader may be desirous of knowing something of the history of the conduct and progress of an undertaking, which had so great an influence on the current of public opinion; and the *Memoires* of Baron

Grimm, lately published, have furnished us with some anecdotes relative to the publication, not previously brought to light, which are too curious to be omitted.

M. le Breton, first printer in ordinary to the king, had an interest, to the extent of one half, in the profits of the Encyclopædia, and was besides charged with the printing of the whole work. The other half was shared among three booksellers, two of whom died; in consequence of which, le Breton and Briason came to be the exclusive proprietors of the whole. These two individuals, therefore, divided among them the whole profits of the work, leaving to Diderot all the glory, the danger, and the persecution. His stipend, as editor of a work which occupied one half of his life, was fixed at 2500 livres for each of the seventeen volumes of treatises, and a sum of 20,000 livres in one payment. The Encyclopædia, from its commencement, had incurred the censure of government, and been made the object of proscription. In order to prevent new prosecutions during the further progress of the work, it was resolved to publish the ten last volumes together; and with a view to procure a knowledge of the seizures ordered by the police, and to avoid the impediments which fresh informations might throw in the way of the continuation of the undertaking, M. le Breton obtained the censorship of the trade. These precautions insuring safety during the progress of the impression, le Breton became anxious also to avert the storms which he conceived might threaten him after publication; and, for this purpose, he adopted a plan, which is probably unparalleled in the annals of book-making. The different articles were printed off as they came out of the hands of the several contributors; but after Diderot had revised the last proof of each sheet, Le Breton and his associate took possession of the copy, cut, retrenched, suppressed all that appeared to them too bold, or calculated to excite the clamours of the enemies of the work; and thus, of their own authority, reduced the greater number of the best articles to the state of mutilated fragments. The impression was drawing towards a close, when Diderot, having occasion to consult one of his great philosophical articles in the letter S, found it entirely mutilated; and upon further examination, he discovered that the same plan had been pursued in regard to the whole of the leading articles furnished by himself and his ablest co-adjutors. This discovery threw him into a state of phrensy and despair, which may be more easily conceived than described. The evil, however, did not admit of a remedy; the injury that had been committed was irreparable. The manuscripts had been destroyed; and they were already arrived at the impression of the last volume. Besides, the friends of Diderot advised him, for his own sake, to preserve silence in regard to the breach of trust of which the printer had been guilty; because it was impossible for him to make the public acquainted with the facts, without furnishing his enemies with a legal proof of his continuing to be the editor of the dictionary, after it had been suppressed by authority, which would probably have forced him to quit his native country. It is remarkable, as Baron Grimm observes, that no complaint on the subject of these proceedings was ever uttered by any of the authors of the different articles, and that the fact of the mutilation was never known to more than four or five individuals.

To the *Dictionnaire Encyclopedique,* Diderot devoted the labour of almost twenty years; during which period he, however, found leisure to publish several separate works, some of which were useful and creditable to his talents; while others, particularly his *Bijoux Indiscrets,* proved detrimental to his own reputation, and injurious to the morals of his countrymen. The Encyclopædia, although a very popular work, was, as we have seen, profitable only to the booksellers, and produced to the editors no adequate remuneration for the time and labour which they had bestowed upon it. * After it was brought to a conclusion, Diderot's affairs were so much involved, that he was obliged to come to the resolution of selling his library, which was purchased by the Empress Catherine of Russia; who, with a rare liberality that does credit to her memory, paid him 50,000 livres for it, or, according to Baron Grimm, 66,000 livres, and, at the same time, allowed him to retain the use of it during his life.

Diderot seemed more desirous of resting the reputation of his literary character on his productions in the department of the *belles lettres,* than upon his scientific labours. When he produced his two comedies, *Le Pere de Famille,* and *Le fils Naturel,* he wished to be considered as the inventor, as he was the eulogist, of that species of the drama, which is known among us by the name of *sentimental comedy,* and which the French denominate *Comedie larmoyante, Tragedie domestique,* or *bourgeoise.* But this kind of comedy had been previously introduced by Paul Landois, an obscure and now almost forgotten author; and afterwards attempted, with more ability and greater success, by La Chaussée. The comedies of Diderot do not exhibit much dramatic genius. His dialogue is stiff and sententious, and his characters too romantic for real life.

Diderot published several memoirs on mathematical subjects. He applied himself particularly to the study of music, and drew up, in dialogues between master and pupil, a luminous and pleasing treatise on the elementary principles of that science, and the art of performing on the piano-forte. Among his miscellaneous works, there is also an excellent essay on acoustics. Besides, he is said to have left behind him in manuscript, a quantity of observations on music sufficient to fill a quarto volume.

The fame of Diderot will perhaps be found ultimately to rest, in a great measure, upon the share he had in the publication of the *Dictionnaire Encyclopedique.* During his lifetime, he probably owed much of the reputation he enjoyed, to his talent for that species of animated conversational eloquence, which is capable of communicating its own enthusiasm to all around, and which is better adapted to the social circle or the literary *coterie,* than to the study of the man of science. His style of writing is by no means correct. He frequently endeavours to clothe common-place ideas in pompous language; and, although sometimes luminous and instructive, he is often obscure, feeble, superficial, and affected.

He died suddenly as he was rising from table, in the month of July 1784. (*z*)

DIDO. See CARTHAGE, p. 560, 564.

DIDYMANDRA, a genus of plants of the class Polygamia, and order Monœcia. See BOTANY, p. 343.

DIDYMELES, a genus of plants of the class Diœcia, and order Monandria. See BOTANY, p. 333.

* Voltaire mentions, that four editions of this work, which had been proscribed in France, were printed abroad; and that about eighteen hundred thousand crowns thus went into the pockets of foreigners. See Grimm's *Memoires,* vol. i. p. 344.

Didymus || Van Diemen's Island.

DIDYMUS' GENERA, in Music, were among the many modes which the theoretical writers on the Greek scales had, of dividing the tetrachord, or minor fourth. According to Dr Wallis, the genera of this author were as follows, viz.

$$\text{Enharmonic } \tfrac{31}{32}\times\tfrac{30}{31}\times\tfrac{4}{5}=\tfrac{3}{4}=\text{4th.}$$
$$\text{Chromatic . } \tfrac{15}{16}\times\tfrac{24}{25}\times\tfrac{5}{6}=\tfrac{3}{4}$$
$$\text{Diatonic . . } \tfrac{15}{16}\times\tfrac{9}{10}\times\tfrac{8}{9}=\tfrac{3}{4}$$

Two of these in the enharmonic, involves primes higher than 5, and are inconsistent with our present music. (e)

DIDYNAMIA. See BOTANY, p. 74 and 242.

DIEMEN'S ISLAND, VAN, is an island which, from the year 1642, was believed to be an integral part of New Holland, until recent observations have proved its separation from that extensive territory by a channel called Bass' Straits, bounding it on the north. It approaches to a rectangular form, being about 160 miles in length, and 80 in breadth; and its most southern point, Cape South, lies in 43° 42′ South Lat. and 146° 56′ East Long.

This island is surrounded by several others of various sizes, such as De Witt's isles, Schouten's, Bruny's, and Maria's islands to the south and east; and those of Furneaux and others to the north. Bruny's island is of a very singular appearance, consisting of two high mountainous territories, separate and distinct for a considerable interval, but connected by a low narrow neck of land; on the eastern coast of which is Adventure Bay, a port hitherto erroneously described as pertaining to Van Diemen's Land: but Bruny's island is divided from it by a channel discovered by the French in 1791, and named by them D'Entrecasteaux's Straits. In general, isthmuses are common on the coast, and frequently terminate by a high promontory: Even Van Diemen's Land presents a bold and rugged front to the southern ocean; lofty basaltic columns resist the turbulence of the waves, and the proximity of sterile pointed rocks, detached from the main-land, attest, that their separation has been effected by continued tempests, or some catastrophe of nature. Nevertheless, its shores are in many places penetrated by deep and capacious bays, forming safe harbours for shipping, and occasionally fresh water streams are discharged into them. The interior consists of ridges of mountains, some almost bounded by the sea, interspersed by extensive plains and vallies of rich vegetable soil. Salt and fresh water lakes appear covered by innumerable birds; but, as on the continent of New Holland, there are few rivers, and scarcely more than one or two for a short distance navigable.

Climate.

The climate, in general, is temperate, though chill and stormy about the southern extremity, except in the summer season; and snow lies on the mountains during several months of the year. Sometimes hot and sickly winds blow impetuously from the north, resembling the air at the mouth of an oven: the whole human body feels as if in a vapour-bath; vegetation is then totally blighted, and the putrefaction of animal substances accelerated in a remarkable degree.

Mineralogy.

The mineralogy of this island has not yet been sufficiently explored, to enable us to speak of it in detail. Metallic indications are rare, schist and granitic rocks abound, small quantities of coral have been discovered, and petrifactions of wood and shells are found at a great height above the level of the sea. But it is otherwise with the animal and vegetable creation; there immense variety appears, all new and unknown on the old continents of the world. Trees attain the incredible size of 180 feet in height, and 36 in circumference, and exhibit, in their decay, the evidence of the most remote antiquity. While the top is still in foliage, the trunk has wasted away to a slender ring, affording, in the interior cavity, an insecure habitation to the rude natives of this distant region.

Forests.

"The dark forests of Van Diemen's Land present a remarkable spectacle: These are the ancient offspring of time and nature, where the blow of the axe has never resounded; where unrestrained vegetation, daily becoming richer from its own products, meets with no obstruction; and which excite still greater interest, from consisting exclusively of trees unknown in the civilized world, and vegetables singular in organization. There a mysterious gloom perpetually prevails, a refreshing coolness, and a penetrating humidity; there, are overgrown trees mouldering down with age, from which so many vigorous scyons are springing; mosses and parasite lichens cover the massy trunks, now decomposing by the united action of time and moisture; while cold bodied reptiles or insects are harboured within in legions. All the avenues of the forest are obstructed by them; they cross each other in a thousand fashions, forming so many protecting barriers, which oppose the progress of the traveller, and multiply the dangers around him. Sometimes the slippery and decaying bark yields under his feet, or, sinking by his own weight, he is buried amidst the surrounding fragments. Sometimes they are heaped together in ramparts of twenty-five or thirty feet in height; or, fallen over the bed of torrents, they constitute so many bridges, which the passenger must cross with distrust. But amidst this scene of ravages and disorder, nature universally rears all that is most imposing by her creative power. Every where are seen in flourish, beautiful mimosas, superb metrosideros, and elegant correa, which are strangers to our native regions." Yet in this profusion there is scarcely a vegetable adapted for the sustenance of mankind; for, excepting the rarest instances, neither roots nor fruits have been discovered which may be converted to that purpose. The soil, besides, though in many places rich, owes its chief fertility to the immediate decomposition of vegetable matter.

Fishes.

The mollusca tribes, in the neighbouring seas, are innumerable, and have added infinitely to that branch of natural history which is still so imperfectly illustrated. Quantities of fish approach the shores, and, at certain seasons, may be taken with much facility; at low water, abundance of oysters, mussels, and the like, are procured of the finest quality; and many curious shells, which have lost their inhabitants, are washed up by the tide.

The cetacea are likewise very numerous in the vicinity; and the phocæ, sometimes almost covering the desert islands, have afforded an opportunity of establishing profitable fisheries.

Birds.

Uncommon beauty and variety are displayed among the feathered race: Besides the birds, of which analogous species are seen in Europe, there are cocatooes, black-spotted parroquets, pelicans, and the black swan, so long thought to exist only in fable. Flocks in hundreds cover the lagoons, where they shew wonderful sagacity in evading pursuit; and if followed by a boat, instead of directing their course straight forward to escape, always endeavour to gain the wind to aid their progress.

Nature has been peculiarly sparing in the distribu-

Van Diemen's Island.

Quadrupeds.

tion of quadrupeds in Van Diemen's land and its adjacent islands; but none of the few that are found there are said to exist on the old continents. The kangaroo, which is most numerous, is a quadruped resembling an enormous rat, with the fore legs so short that it can scarcely, if ever, use them in running; nevertheless its speed is considerable, and it can leap to a great distance when hunted. Its common progression is on the hind legs only, and it can rest unsupported by them on the root of a strong, broad, and muscular tail. The kangaroo forms paths through the thickest part of the brushwood, which commonly terminate at a rivulet. The wombat, an animal of equally singular structure, belongs exclusively to these regions: it is low and squat, the size of a turn-spit dog, weighs between twenty-five and thirty pounds, and has hardly any perceptible tail; the face of a triangular figure, somewhat resembling that of a cat, and is provided with strong whiskers. It burrows in the earth, perhaps as a retreat in time of danger: it is an extremely mild and docile animal, and now is seen in a domesticated state among the British settlers. We have also indistinct accounts of some other animals, such as that called the porcupine ant-eater by Mr Bass and Captain Flinders, which burrowed by sinking backwards among light sand, and always presented its prickly back to their dogs, which were unable to make any impression on it. M. Crozet speaks of a tiger cat, and the print of a carnivorous animal's foot as large as that of a dog. M. Labillardiere and M. Rossel saw the bones of a carnivorous animal; and a very fierce creature, described as a hyæna, is reported lately to have been discovered in the north parts of the island. Farther information, however, is necessary before naturalists can decide on the genus to which it pertains.

Inhabitants.

The inhabitants are also scantily disseminated throughout Van Diemen's Land; nor, without the benefit of civilization, is the country adapted for a numerous population. Some slight differences apparently exist between their structure and that of the inhabitants of other parts of the world, and even those of the neighbouring coast of New Holland. The head is of great size, and of uncommon length from the chin to the sinciput; the upper jaw of children projects, but resumes the ordinary shape in adults; the shoulders are broad, the thighs fleshy, but the legs and arms are slender, and deficient in that muscular consistence which is proper to the human extremities. The belly also is large, prominent, and exhibits a kind of unnatural intumescence. Various speculations have been indulged respecting the cause of these appearances; the former is thought to result from sparing and unsuitable aliment, added to the difficulty of obtaining it; and the latter, though with little likelihood, is ascribed to the want of compression from apparel. These people have woolly hair, their skin is not of a deep black, and their teeth are rather large and white. They are hardy and robust, going totally destitute of clothing even in the severest weather; but their personal strength is inferior to that of Europeans. Many of the women, however, have the skin of a kangaroo thrown across their shoulders, principally for the purpose of supporting their children; and some of the men are occasionally seen with the same habiliment. The latter allow the hair of the head and beard to grow; it is bedaubed with grease and red ochre, forming into a filthy matted heap. The women crop their hair close, and wear a string around the head. Both sexes blacken the skin with a composition of grease and very fine charcoal, or plain charcoal rubbed down between their hands, an ornament which they are very fond of bestowing on their European visitors. They tattoo themselves with great symmetry, the skin rising in low tubercles, though of the same colour as the rest, and the women form three semicircular lines of this description across the abdomen. The natives of Van Diemen's Land are altogether unskilled in the arts. In the lowest stages of ignorance and degradation, they have not even learned to secure their persons by clothing from the inclemency of the elements. Their habitations are only rude barriers against the wind, from which they shelter themselves on the opposite side; or they take refuge in the cavities of the enormous trunks of decaying trees, which they contrive to enlarge by fire. These excavations, which are of such a size that several men may be stretched at length within their bounds, always open from the east, probably to protect their tenants from the more prevalent storms, or it may be that decay commences in that quarter first. Seven or eight of their miserable huts, if such they can be called, or even fourteen, stand together; they are constructed of bark torn in long stripes, after being cut below, from some neighbouring tree, and of such breadth that the strength of their arms enables them to detach it from the wood. This bark is then broken into suitable lengths, and placed in an inclined position against the elbowing part of a dead branch that has fallen from the distorted limbs of the gum tree; and the pieces are so adapted as to preclude the access of rain.

Utensils.

These people can scarcely be said to possess tools or utensils. By means of a fragment of granite, or a shell sharpened on the edge, they detach the bark for constructing their dwellings, and also form short clubs and lances, which latter are from 16 to 18 feet in length, besides another implement, a wooden spatula, to remove shell-fish from the rocks. Their baskets are made by tying the two ends of a large bunch of long wiry grass to the two ends of a smaller bunch; the large bunch spread out constitutes the basket, while the smaller bunches serve for a handle. Notwithstanding this rude and original contrivance, baskets made of reeds, of very elegant and singular construction, have been seen among them. A drinking vessel, or one to carry water, is obtained by thrusting two wooden pins through the edges of a large flat leaf of sea-weed, which, being closed together on the pins, forms a sufficient cavity.

Canoes.

Some of the natives have slight canoes, from seven to nine feet long, formed of slips of the bark of trees, woven together with reeds, and tied up at the ends. In these frail embarkations they commit themselves to the waves; and in case of surprise, remove them from the water, and speedily run into the woods with them on their heads. But it does not appear that such belong to all the different tribes on the mainland, and they are more common on the detached islands surrounding its shores.

Customs.

The inhabitants of Van Diemen's Land constitute erratic hordes, united by no bond of common interest, except the facility of procuring sustenance. Perhaps they have inland dwellings, as yet unknown to strangers; for at certain seasons of the year they resort towards the coast, when the smoke of their fires, at first seen at great intervals, which daily diminish, is at length more concentrated towards the south or eastern points of the island. It has been remarked, that they constantly hover over large fires, though without any apparent necessity, and that such are kept burning day and night around them. They subsist almost entirely on shell-

Van Diemen's Island.

fish, the charge of procuring which devolves on the women, as well as its future preparation. Each, on these occasions, provides herself with a basket, and leaping from a rock into deep water, detaches them with her wooden spatula below. This is severe and exhausting labour; the women return to the surface only to breathe until their baskets are full, and they remain so long at the bottom, that European spectators are wont to be alarmed lest they have been entangled among the weeds, or have become a prey to ravenous fishes. Daughters are employed along with their mothers, and their collections are first brought as a tribute to the men. On emerging from the water, they carefully dry themselves before fires, and then prepare their food, which consists of lobsters, oysters, mussels, and chiefly of the ear shell. During their repasts, which continue remarkably long, each family separates from the general horde, and gathers round the fire to partake of it. But the labour has to be daily renewed, as little provision is made for future necessities. Nothing is grateful to the Diemenese that is used by Europeans: bread is rejected, nor will they permit their children to taste it. The women are apparently in absolute subordination to the men, and bear many indications of their savage ferocity. But the men are in no subordination to each other; they are void of all laws, regulations, or goverment, so far as is hitherto ascertained; they exist on the most perfect equality: nor do the whole people admit of any controul, except of husbands over their wives, and parents over their children. The nature of the alliance between the sexes is not clearly understood. Doubts may be entertained whether it be permanent; and although some transient visitors have conjectured that polygamy is practised among them, such opinions rest on a very slender foundation.

Custom of burning the dead.

A remarkable custom, that of burning their dead, is found among these savages; thus exhibiting in the rudest stages, what has been peculiar to men in the highest state of civilization. We are unacquainted with the detail of cremation, or whether it is practised after the same manner as on the coast of New Holland; but the ashes collected together are deposited in a small circular excavation, not exceeding eighteen inches in diameter, and ten in depth. A conical structure, neatly composed of bark, supported by poles below, and tied round above, is erected to cover them; and a sequestered spot, near some limpid rivulet, seems chosen for the purpose. Nevertheless, such structures, as also the remains of the dead, are of rare occurrence, even compared with the scanty population of the country. That they should be so, is in this manner explained from their nature: "The bark, by which they are protected, cannot fail to be speedily destroyed by the action of the atmosphere, or dispersed by the winds. The tender and delicate grass covering the ashes is likewise soon decomposed, and the ashes themselves, already partly scattered, can only present the appearance of a fire having been kindled on the spot; for the bones gathered together in the bottom of the excavation remain buried in the earth. None are therefore found on the surface; and we may add, as another reason, that the powerful calcination they have undergone renders their annihilation more immediate and complete."

Language.

Very litttle is yet understood of the language of the Diemenese, except that it abounds with vowels, is faintly articulated, and uttered with the greatest rapidity. It differs from that of all the surrounding nations.

Manners of the inhabitants.

Nothing has been more disputed than the natural character of man. Some have maintained that he is born, kind, tender, and benevolent, prone to the exercise of virtue; while others have contended, that vicious habits implanted in him, are displayed by ferocious cruelty and arrogance. But it is ignorance of the real savage state which has disguised the truth; and those opinions favourable to the disposition of our race, have been established on the early acts of docile children sprung from virtuous parents. Man, by nature, is sanguinary and tyrannical; and although none have yet been seen in stages of absolute degradation, void of every bond of union, and each providing solely for himself, still their inherent malevolence seems proportioned by their approaches to it. In general character, the natives of Van Diemen's Land are a lively people; they are frank and courteous to strangers, and ready to associate with them. Apparently they are divested of that cunning, and the love of vengeance, which actuates all other savages. Like children, they are occupied with novelties for the moment; and what is prized by them as a precious possession to-day, is thrown aside, or viewed with perfect indifference, to-morrow. The women are affectionate to their children, but the men are tyrannical to their wives; an infallible test of uncivilized society. Notwithstanding their evident placidity, their ready reception of strangers, and the willing assistance lent to them on all occasions, they are ever to be met with distrust; for treachery, if not invariably predominant in their thoughts, is too often only awaiting an opportunity to be practised. But these facts will be better illustrated, in taking a cursory sketch of the history of this territory, which, from various circumstances, has attracted unusual attention in Europe; partly excited, indeed, by the errors that have prevailed, and which even now prevail, concerning it.

Progress of discovery.

Abel Jansen Tasman, a Dutch navigator, being sent out on a voyage of discovery by the governor of Batavia, when in latitude 42° 25′, saw land ten miles distant, which, in honour of the governor, he named Van Diemen's Land; and on the 24th of November 1642, anchored in a bay, called by him Frederic Henry's Bay. He took possession of the country, by displaying the colours of his nation, and marking a post with the arms of the East India Company. Tasman saw no inhabitants; but remarking notches or steps five feet asunder on trees, he concluded that either they must be of extraordinary stature, or that they adopted some uncommon expedient for climbing them.

Tasman, 1642.

Possibly other navigators might visit these distant regions, more especially in the course of that numerous succession of voyages which we have historically enumerated in our general view of Australasia. But the next distinct account given of an inconsiderable portion of this island, is in a voyage by M. Marion du Fresne, a French officer, who unfortunately perished soon after.

Marion du Fresne, 1772.

On the 3d of March 1772, M. Marion came in sight of Van Diemen's Land, and brought his vessel to an anchor in Frederic Henry's Bay. Fire and smoke, seen the preceding day and night, announced that the neighbourhood was inhabited, and the herbage and foliage on the coast wore an inviting aspect. Thirty of the natives appeared and received their visitors, who had now reached the land, without any indications either of friendship or hostility. All were completely naked. The French, to gain their favour, offered them looking-glasses, handkerchiefs, and pieces of cloth, but every thing was rejected with contempt; nor would they accept of poultry, which had been brought from the ship. Their

Van Diemen's Island.

meagre appearance, broad shoulders, and woolly hair, struck the French; but the Diemenese expressed no signs of astonishment during the interview. Previous to this, a quantity of dried wood had been collected by the savages for a fire; and one at length separated from the rest to present a fire brand to M. Marion, and others, that they might set it in flames. M. Marion, considering this procedure to be a token of pacification, did not hesitate to apply the brand; but his error was quickly demonstrated, for kindling the fire seemed to prove a signal of defiance. No sooner had he done so, than the natives precipitately retired, and, from an eminence, saluted their visitors with a shower of stones, whereby he and their officer were wounded. The French immediately retaliated by a discharge of musketry, and then sailed along the bay to a supposed place of security. The savages followed, however; and having sent the women and children into the woods, opposed their landing by a flight of lances, one of which took effect. A second discharge of musketry killed one and wounded several of their number, whereupon, uttering hideous yells, they fled into the interior. These unprovoked aggressions established the real character of the Diemenese, which has sometimes been so egregiously mistaken; and future navigators may safely conclude, that the spears of savages are less designed for the destruction of wild animals, than for warfare with their own species.

Furneaux, 1773.

A year afterwards, Captain Furneaux, in the course of Captain Cook's second voyage of discovery, arrived at Van Diemen's Land; and in 1776, Captain Cook anchored there himself. He remained a few days, and had frequent interviews with the natives, by whom he was well received, and who approached him with perfect confidence. Nothing was known to him of M. Marion's adventure, which is not surprising, as no account of his voyage was then public, nor is it known even at this day in Britain, except to a few individuals; his anchorage besides was not in the same place. Captain Cook proposed to have set ashore a bull and cow, together with some sheep and goats; but apprehending they would be destroyed by the natives, he let loose a pair of pigs only.

Cook, 1776.

Scarcely any part of this country was explored, except the southern extremity and Adventure Bay, together with some of the adjacent islands; but it appears that European vessels occasionally touched on the coast. Captain Bligh, in completing the original purpose of his voyage for bringing the bread fruit tree from the Friendly Islands to the West Indies, anchored at Van Diemen's Land. His botanists planted several fruit trees and useful vegetables here in the year 1792, to which the soil and climate seemed well adapted.

Bligh, 1792.

Entrecasteaux, 1793.

Shortly after Captain Bligh's departure, two French vessels, under the command of Admiral D'Entrecasteaux, who had been sent out in quest of M. de la Perouse, reached Van Diemen's Land: a considerable portion of 1792 and 1793 was occupied in observations on the country, its products, and the disposition of the natives. But above all, an accurate hydrographical survey was made of the coast and islands, the result of which has lately appeared in a magnificent collection of engravings, executed by the order and at the charge of the present French government. Various learned men had, with laudable attention, been associated with the expedition; and by their united labours, an intimate acquaintance, compared with what was previously known of the Australasian regions, was obtained. The errors of Captain Cook and preceding navigators were corrected; and it was ascertained, that a considerable channel, which the French named D'Entrecasteaux's Straits, separated the adjacent islands on the east from the main land. They were received without reserve by the inhabitants, who assisted and promoted their objects; and certainly, on this occasion, manifested no symptoms of treachery, though they had their visitors completely in their power. In addition to planting such vegetables as were likely to prove useful to later navigators, the French set two goats at liberty, in hopes that their offspring might supply their wants.

Conjectured to be an island, 1797.

Van Diemen's Land was still believed to be the southern portion of New Holland; nor had navigators suspected any existing channel by which they were separated. "I need hardly say," Captain Cook observes, "that it is the southern point of New Holland, which, if it doth not deserve the name of a continent, is by far the largest island in the world." But in the year 1797, a vessel having been wrecked considerably to the south of Port Jackson, on an island, since called Preservation island, part of the crew were left there, while the rest went in quest of assistance. During the interval, they made some excursions in a small boat in different directions, and from their report, and other circumstances combined, the governor of the settlement conjectured, that there might be passages or straits running westward to the ocean, whereby Van Diemen's Land would be separated from the south coast of New Holland. These conjectures were further corroborated in the subsequent year, by Mr Bass, surgeon of the Reliance ship of war, who, during a voyage of twelve weeks in an open boat, sailed as far as 40° of south latitude. He visited every opening in the way; and from all his observations, concluded, that there was a channel between 39° and 40° of south latitude, rendering Van Diemen's Land an island; and he thought he might have performed a complete circumnavigation, had he been provided with a better vessel. In the end of the same year, Mr Bass had the satisfaction of ascertaining the truth. Accompanied by Lieutenant Flinders of the navy, he penetrated the supposed entrance into the channel, circumnavigated Van Diemen's Land, and returned to Port Jackson, from whence the voyage had been undertaken, early in January 1799. The period of the excursion had been limited by the governor to twelve weeks; but in the course of that time, in addition to the more important discovery of the main object in view, the navigators gained an acquaintance with many parts of the island which had never been previously visited. They opened a wide field of observation, and in the comparisons which were drawn between the territorial advantages enjoyed by the colony at Botany Bay, it became a subject of contemplation, whether subordinate settlements might not be profitably established on Van Diemen's Land. Scarcely any thing, however, except the margin of the island, had been visited: the natives were seldom seen, and very little knowledge obtained of their manners.

Discovered to be an island by Mr Bass, 1798.

Flinders, 1799.

Another expedition was planned by the French about the same period, of which the ostensible purpose was the promotion of scientific discovery: and certainly nothing was spared which, in this respect, might promise success. Twenty-three individuals embarked, whose sole province was to explore the nature and peculiarities of the regions they were to traverse; out of these, only three returned to their native country. Nevertheless, the object of their united labours was preserved, and we are thence enabled to judge of the research as bestowed on the island now under our considera-

Van Diemen's Island, Dieppe.

tion. The geographical discoveries are, perhaps, of less importance than those which were made in natural history, or there might be less opportunity for them, after the surveys of D'Entrecasteaux, particularly to the south and south-east of the island. Part of the years 1801 and 1802 were occupied in circumnavigation, and in observations on the coast. Some geographical errors were corrected, and the French ascertained, that several of what preceding navigators had supposed adjacent islands, were only so many lofty mountains, connected by isthmuses to the shore. But they made numerous and rich collections of the products of Australasia, both aquatic and terrestrial, from which many genera and species, heretofore unknown, have been constituted. Their interview with the natives, conducted with every precaution, led to the same conclusion that we have deduced from their conduct to M. Marion, that, although at one instant they prove courteous and amicable to strangers, in the next their innate treachery and ferocity will appear. The French had good reason to be satisfied, that none of their numbers fell victims to such a malevolent race. Yet various tribes may differ in character; and even comparing all that has been experienced from the Diemenese with the demeanour of many other savages, they are infinitely to be preferred. While some approached without reserve, others anxiously shunned their visitors, and retreated with loud clamours to the mountains. The whole country was set in flames, as if they were content by that sacrifice to drive them away; and they seemed to shelter themselves amidst columns of fire and smoke. Sickness compelled the French to abandon their researches on Van Diemen's Land, which were resumed at various intervals in the course of the voyage. Only part of their discoveries have hitherto been made public; and the death of M. Peron, in December 1810, interrupted the work devoted for that purpose; but the remainder, we have understood, was far advanced a considerable time ago, and was to be completed by one of the literati of the expedition, sufficiently qualified for the task. More recently, a British settlement has been established on this island, which is divided into different counties; two towns are founded; and the whole is said to be now in a flourishing condition. See Tasman's *Voyage; Nouveau Voyage a la Mer du Sud*; Collins' *Account of Botany Bay*, vol. ii.; Cook's *Third Voyage*, vol. i.; Peron *Voyage aux terres Australes*; La Billardiere *Voyage*; Rossel *Voyage de Dentrecasteaux*, tom. i. p. 54, 213; and *Memoire sur la vie*, de Peron. An account of the Botany of New Holland will be found in R. Brown's *Prodromus Plantarum Novæ Hollandiæ et Insulæ Van Diemen*, London, 1812. The plants which that able botanist discovered in this island, are likewise noticed in our article Botany. See also the articles Australasia, Maria's Island, and Preservation Island. (*c*)

DIEPPE, a sea-port town of France, in the department of the Lower Seine, and the principal place of a district of the same name, is situated between two rocky mountains on the English Channel, at the embouchure of the river Arques. The town is handsome and well built, and the streets are regular, straight, and spacious, particularly the high street, which is about a mile long. To an English eye, however, the aspect of the town is by no means agreeable, the fronts of the houses are black, the windows frequently filled with clothes hung out to dry, and the corners disfigured with spiders and other vermin. The pavement is also very inferior to those in English towns, the streets being cleaned by gutters running down the middle, with cuts on each side leading to the houses. The town has two suburbs, one of which, called the Paulet, is inhabited principally by fishermen and sailors. The principal public buildings are the parish church of St James's, which is a fine edifice, and from the tower of which the English coast can be distinctly seen; and the old castle, at the western end of the town, which is very badly fortified. Besides these buildings, there are two parish churches; nine religious houses, an hospital, and a hotel-dieu. There is a pleasant promenade on the ramparts.

Dieppe, Diesis.

The harbour, at the east end of the town, is in the form of a semicircle, has about 18 feet at high water, and has two very fine moles of strong brickwork about half a mile long. It contains only about 200 vessels of not more than 400 tons burden.

The principal manufactures of Dieppe are those of thread, lace, ivory and horn toys, and barrels. In the year 1788, the lace manufacture gave employment to about 4000 females and children, who were mostly the wives and daughters of fishermen, and its annual amount was estimated at 400,000 livres. It belongs to about 50 merchants established in Dieppe, who found a vent for it in the interior of the kingdom, in Spain, and in the American islands. The articles in ivory and bone are wrought with great skill, and sold at a very reasonable price, a figure of 8 or 10 inches, well finished, costing only about six livres. In the manufacture of barrels for the fisheries, more than 400 master coopers are employed.

The herring, whiting, and mackerel fisheries, are carried on to a great extent in Dieppe. During the nine years from 1781 to 1789 inclusive, about 58 vessels at an average were employed in the herring fishery, which produced at an average 6206 lasts of fish, worth about 1,820,900 livres. During the peace of Amiens, only 40,000 barrels were caught. The mackerel fishery, which employs about 45 vessels, produces annually about 280,000 livres, and the whitings, which are caught in December, January, and February, are sent to Paris in light carts, which travel both night and day. There are regular packet boats, in time of peace, between Dieppe and Brighton, a passage of 66 miles, which generally occupies from 10 to 24 hours. Population 20,000. East Long. 1° 4′ 44″, and North Lat. 49°55′ 34″. High water at spring tides 10^h 30′. A copious history of the trade and commerce of Dieppe will be found in Peuchet's *Dictionnaire de Geographie Commerçante*. See also Herbin *Statistique de la France*, and a *Tour in France in August* 1789. (π)

DIESIS, in Music, was originally, we are told, intended by the Greeks, to express certain intervals larger than a comma, but smaller than a semitone; yet this distinction has not been adhered to by more modern writers: but a great number of small intervals, and some larger, have received this name, and it is very necessary that the musical calculator should be apprised of these, which can only be done by having them expressed in the same notation, and placed in alphabetical order, as follows:

DIESIS of Boethius, and which also has been called by some, his diaschisma and his semitone minor, is the half limma (or $\frac{1}{2}$ L) $= 22.9251695\Sigma + f + 2$ m, or $23\Sigma + \frac{1}{2}f + 2$ m, and its common log. is .9886813,5414. It is $= \frac{1}{4}t - \frac{1}{4}\Sigma$, and its approximate ratio, found by our theorem in the article Diaschisma, is $\frac{985}{1011}$ very nearly.

DIESIS of Euclid, in his enharmonic sescuplum genus, is stated to be sesquialtera to the enharmonic diesis, (or $\frac{3}{2}\mathcal{E}$) = 31.35082014Σ + f + 2m, or $31\frac{1}{2}$Σ + 3m, and its log. = .9845500,6504.

DIESIS of Mercator, according to Dr Holder, is $\frac{2}{53}$d parts of the octave, = 2 of his artificial *commas*, = 23.0124496Σ + f + 2m, or $23\frac{5}{53}\Sigma + \frac{20}{53}L + 2m$, and its log. = .9886403,7752 = .03773584 × VIII, = 2.1055714 × c.

DIESIS CHROMATIC of Dr Calcott, (∂) its ratio is $\frac{16384}{16875}$ = 26Σ + 2f + 2m. See CHROMATIC *Diesis.*

DIESIS CHROMATIC of Hoyle ($\frac{1}{2}$T) has a ratio $2\sqrt{2} \div 3$, = 52.0039312Σ + f + 4m, or 52Σ + f + $4\frac{1}{2}$m, its common log. = .9744237,3877, its Euler's log. = .084962, and its major comma log. = 4.74070.

DIESIS DOUBLE ENHARMONIC, (or 2 $\mathcal{E}$) has a ratio $\frac{15625}{16384}$ or $\frac{5^6}{2^{14}}$ = 41.858201Σ + f + 3m, or 42Σ + 4m, and its log. = .9794000,8672; it is = S + R, = f + € = đ + 3 € = S — ∂, = 4c — 2Σ, = 2t — 4S, 4đ — 6Σ, = 4S — 2t = S — π, = 2 6ths — 4 IIIds = 2 VIII — 6 III, by either of which two last equations, it may be tuned on an instrument like Mr Liston's organ.

DIESIS DUODECIMAL of Aristoxenus, used in forming his genera or scales of music, and said to be practised by the Greek musicians, was $\frac{1}{30}$th of the minor fourth, = 8.489514Σ + m, or $8\frac{7}{15}\Sigma + \frac{1}{6}f + \frac{11}{15}m$, and its log. = .9958353,7545. Dr Holder informs us, that this interval was so named, because it was thought to be the twelfth part of the major tone; but the latter exceeds the former by more than $\frac{1}{5}$Σ, or .200131Σ. It is = .0138346 × VIII = .771937 × c = 8.497376 × Σ.

DIESIS ENHARMONIC, (or $\mathcal{E}$), has the ratio $\frac{125}{128}$ = 21Σ + 2m. See ENHARMONIC DIESIS.

DIESIS, GRAVE, of Liston, and his grave diminished second, (or €), = $\frac{2025}{2048}$ = 10Σ + m, or the COMMA MINOR, which see. Mr Liston observes, that this interval is near $\frac{1}{10}$th of a major tone, but which is 10.762226Σ + m.

DIESIS, GREATER, of M. Capella, is represented to be $\frac{1}{38}$ (XII — 19$\mathcal{S}$), or 7.524038Σ + m.

DIESIS, GREATER ENHARMONIC, of Hoyle, ($\frac{3}{4}$T) = 78.0728649Σ + f + 7m, or 78Σ + $1\frac{1}{2}$f + $6\frac{3}{4}$m, and its common log. = .9616356,0816.

DIESIS, GREATER ENHARMONIC, of mean tone temperament, 21Σ + 2m (or $\mathcal{E}$). See DIESIS OF TEMPERED SCALES, and our article ENHARMONIC DIESIS.

DIESIS, GREATER, of Quintilian, according to Dr Wallis, had a ratio $\frac{34}{35}$, = 25.52019Σ + f + 2m, its log. being .9874108,7269.

DIESIS, GREATER, of Rootsey, and which he also calls a quarter of a tone, and also an enharmonic semitone, has a ratio $\frac{42}{43}$, = 20.835156Σ + 2m, and its log. = .9897808,3482.

DIESIS, LESSER, of M. Capella, is stated to be $\frac{1}{34}$th (11th — 17S), or 7.468275Σ + m.

DIESIS, LESSER CHROMATIC, of Chambers, Good, Holder, &c. (or S), has a ratio $\frac{24}{25}$ = 36Σ + f + 3m. See SEMITONE MINOR.

DIESIS, LESSER ENHARMONIC, of Hoyle, ($\frac{1}{4}$T). See DIESIS QUADRANTALIS of Euclid.

DIESIS, LESSER ENHARMONIC, of mean tone temperament, which falls between ※B and ♭C, and between ※E and ♭F, where the half tones are situate, is = 17.8937641Σ + 2m, or $17\frac{3}{4}$Σ + f + $1\frac{1}{4}$m, and its log. = .9912224,3171. See DIESIS OF TEMPERED SCALES.

DIESIS, LESSER, of Quintilian, according to Dr Wallis, had a ratio $\frac{35}{36}$, = 24.798335Σ + f + 2m, and its log. = .9877655,4358. Mr Holder, in different parts of his works, calls this interval the Accidental Temperament, bearing comma, and quarter of a tone.

DIESIS, LESSER, of Rootsey, and which he also calls a quarter of a tone and an enharmonic semitone, has a ratio $\frac{88}{89}$, = 8.988363Σ + m, and its log. = .9955908,8108.

DIESIS, MAJOR, of Lord Brouncker, Holder, &c. (S), = $\frac{24}{25}$, = 36Σ + f + 3m, or the SEMITONE MINOR, which see.

DIESIS MAJOR, of Maxwell, (€) has a ratio $\frac{2025}{2048}$, = 10Σ + m or the COMMA MINOR, which see.

DIESIS MAJOR, of Quintilian, according to Dr Wallis, had a ratio $\frac{32}{33}$, = 27.10245Σ + f + 2m, or 27.251706Σ + 2m, and its log. = .9866360,3844. M. Chladni observes, that this is the error (※) of the trumpet fourth. See our article CHROMATIC FRENCH HORN.

DIESIS MINOR, of Maxwell (Σ), has a ratio $\frac{32768}{32805}$, = Σ, or the SCHISMA, which see.

DIESIS MINOR, of Quintilian, according to Dr Wallis, had a ratio $\frac{33}{34}$, = 26.28796 + f + 2m, and its log. = .9870350,2284.

DIESIS QUADRANTALIS of Aristoxenus, was $\frac{3}{30}$th of the minor fourth, or $\frac{1}{10}$ × 4th, = 25.32674Σ + f + 2m, or $25\frac{2}{5}\Sigma + \frac{1}{2}f + 2\frac{1}{5}m$, and its log. = .9875061,2634.

DIESIS QUADRANTALIS of Euclid, was one fourth of the major tone, or $\frac{1}{4}$T, = $2 \div \sqrt{2}\sqrt{3}$, = 25.9271353Σ + f + 2m, or 26Σ + $\frac{1}{2}$f + $2\frac{1}{4}$m, and its log. = .9872118,6939. Mr Hoyle calls this the lesser enharmonic diesis.

DIESIS QUADRUPLE ENHARMONIC, (or 4 $\mathcal{E}$) has a ratio $\frac{244,140,625,}{268,435,456,}$ or $\frac{5^{12}}{2^{28}}$, = 83.708541Σ + 2f + 7m, or, 84Σ + 8m; its common log. = .9588001,7344, its Euler's log. = .136861, its schisma log. = 84.062904, and it is = 7.636628 × c.

This interval is an important one, as being the *least sum* of the tierce temperaments, in any douzeave system, or 4VIII — 12III = 4$\mathcal{E}$, on which account it has a place in our Table, Plate XXX. in Vol. II. Dr Boyce, Clagget, and Holder call it a *Note*. The following equations will shew some of its relations to other intervals, viz. 4$\mathcal{E}$ = 7đ + m, = 2S + 2R, = 2f + 2€, = 2S + 2∂, = 2đ + 6€, = 3f — đ, = 4t — 8S, = 8c — 4Σ, = 8đ — 12Σ, = 8S — 4t, = P + 2R + D = 2E + 4€ + 2Σ, = t — 2r — 5Σ, = 8 T — 8t — 4Σ, = 4 3ds + 4 4ths — 8III, = 4 6th — 8III, = 12 6ths — 9VIII, and = 4VIII — 12III, by which last and several preceding equations, this interval may be tuned.

DIESIS SESQUIALTERA of Aristoxenus, in his genus chromatic hemiolion, is reckoned $4\frac{1}{2}$ thirtieth parts of the minor fourth, or $\frac{3}{20}$ × 4th (and was supposed to be one and a half enharmonic diesis, whence the name) = 38.060494Σ + f + 3 m, or $38\frac{1}{10}\Sigma + \frac{3}{4}f + 3\frac{3}{10}m$, and its log. = .9812591,8951. This interval exceeds $1\frac{1}{2}\mathcal{E}$ by 6.606742Σ + m.

DIESIS SESQUIALTERA of Euclid, in his genus chromatic sescuplum, is $\frac{3}{8}$ths of a major tone, or $\frac{3}{8}$T, = 38.965533Σ + f + 3m, or 39Σ + $\frac{3}{4}$f + $\frac{27}{8}$m, and its log. = .9808178,0408. This interval was supposed equal to $1\frac{1}{2}$E; but the latter falls short of the former by 7.607332Σ + m.

DIESIS OF TEMPERED SCALES, are of two kinds, the greater and the lesser. Dr Robert Smith in his *Harmonics*, Prop. III. &c. shews, that in every regularly tempered system the octave is made up of five equal tones, and two equal major limmas, or VIII = 5T + 2L; the difference between these he calls a minor limma, or T — L = l, and the difference between the major and minor limmas, or L — l, he calls the DIESIS (D) of all such scales.

Mr Farey, in a paper in the *Philosophical Magazine*, vol. xxxvi. p. 40, has given several equations or formulæ for adapting Dr Smith's Interval to his notation, and for rendering the calculations of temperaments more easy and useful than heretofore. For this purpose he substitutes $\frac{r}{s}$ and $\frac{t}{u}$ for the fractions of Σ and m, of the temperament of the fifth, in any proposed regular system; each of such tempered fifths being therefore, $V - \frac{r}{s}\Sigma - \frac{t}{u}m$. And he finds

$$\text{In cor. 12.}\quad T = \frac{104s - 2r}{s}\Sigma + 2f + \frac{9u - 2t}{u}m.$$

$$\text{In cor. 11.}\quad L = \frac{46s + 5r}{s}\Sigma + f + \frac{4u + 5t}{u}m.$$

$$\text{In cor. 10.}\quad l = \frac{58s - 7r}{s}\Sigma + f + \frac{5u - 7t}{u}m.$$

$$\text{In cor. 9.}\quad D = \frac{12r - 12s}{s}\Sigma + \frac{12t - u}{u}m.$$

$$d = \frac{70s - 19r}{s}\Sigma + f + \frac{6u - 19t}{u}m.$$

The minor limma or *l*, expressing the value of a *flat* and a *sharp* throughout the scale, the greater *diesis* D, expressing the interval between the *sharps* and the adjacent *flats* of whole notes, or such as are unusually said to be *whole tones* asunder, as between C♯ and D♭, D♯ and E♭, F♯ and G♭, G♯ and A♭, A♯ and B♭, &c. and the lesser *diesis* (now for the first time published) đ, expressing the interval between adjacent *flats* and *sharps* of half notes, or where the *half notes* of the scale fall, as between E♯ and F♭, B♯ and C♭, &c. We will endeavour to explain this, by stating, as an example, the notes of a scale of 24 notes, such as Mr David Loeschman's patent organs and piano-fortes are capable of giving in any proposed temperament, from the *Phil. Mag.* vol.xxxix. p. 418, viz.

C, C♯ D♭, C♯♯ D, D♯ E♭, E F♭, E♯ F, F♯ G♭, F♯♯ G, G♯ A♭, A B♭♭, A♯ B♭, Bc♭, B♯c
l D d D *l* D *l* D d D *l* D d D *l* D *l* D d D *l* D d D

The upper line representing the notes, and the lower one the intervals between every two adjacent ones above.

By counting up the lower ones, it will be seen, that the octave is in this case made up thus, viz. VIII $= 7l + 12D + 5d$; and so it will be found by multiplying the formulas above by these numbers respectively, and adding the products together, viz. that $612\Sigma + 12f + 53m$ will result. Mr Loeschman prefers the *mean tone* system for his instruments, wherein every major third is perfect, and $\frac{r}{s} = \frac{11}{4}$ and $\frac{t}{u} = \frac{1}{4}$. See Mr Farey's 2nd Scholium in the volume first above quoted, which numbers substituted in the formulas above, give

$$l = \frac{232 - 77}{4}\Sigma + f + \frac{20 - 7}{4}m, = 38\tfrac{3}{4}\Sigma + f + 3\tfrac{1}{4}m,$$ the *sharp* and *flat* of this syrtem;

$$D = \frac{132 - 48}{4}\Sigma + \frac{12 - 4}{4}m, = 21\Sigma + 2m,$$ the greater Enharmonic Diesis; and

$$d = \frac{280 - 209}{4}\Sigma + f + \frac{24 - 19}{4}m, = 17\tfrac{3}{4}\Sigma + f + 1\tfrac{1}{4}m,$$ the lesser Enharmonic Diesis, as have been mentioned above.

On instruments which have only 12 notes in the octave, (as is the case on all common organs,) or 14, 16, &c. notes, when tuned to this scale, any of the intervals required may be found by help of the above Table, and values of *l*, D, and đ; thus, if the interval between C and D be sought, it is $l + 2D + d$, which will easily be found $= 98\frac{1}{2}\Sigma + 2f + 8\frac{1}{2}m$; if between C and E, it is $3l + 3D + d, = 197\Sigma + 4f + 17m$, or III, as it should be.

DIESIS Trientalis of Aristoxenus, in his genus chromatic molle, is stated to be four thirtieths of the minor fourth, (and was supposed to be equal to the third part of a tone, whence the name,) or $\frac{2}{15} \times$ 4th, $= 33.81626\Sigma + f + 3m$, or $33\frac{13}{15}\Sigma + \frac{2}{3}f + 2\frac{14}{15}m$, and its log. $= .9833415,0179$. It falls short of $\frac{1}{3}$T, by rather more than $\frac{1}{5}\Sigma$, or $.20052\Sigma$.

DIESIS Trientalis of Euclid, is one third of the major tone or $\frac{1}{3}T, = 2 \div \sqrt[3]{9} = 34.616779\Sigma + f + 3m$, or $34\frac{2}{3}\Sigma + \frac{2}{3}f + 3m$, and its log. $= .9829491,5919$; it is $= .056641 \times \text{VIII}, = 3.16047 \times c$.

DIESIS Triple Enharmonic, (or 3 Ɛ) has a ratio $\frac{1,953,125}{2,097,152}$, or $\frac{5^9}{2^{21}}$, $= 62.858201\Sigma + f + 5f$, or $63\Sigma + 6m$; its common log. .9691000,3008, its Euler's log. $= .1026459$, its schisma log. $= 63.047178$, and its comma log. $= 5.7274715$. The following equations will shew some others of its relations to the other intervals, in Plate XXX. Vol. III. viz. 3Ɛ = S + R, = 3C + 3€, = 6€ + 3Σ, = 6c − 3Σ, = 2*f* − Σ, = 6S − 3t, = 3𝕋 − 6𝕊, = 3t − 6S, = P + φ − ℝ, = 3 6ths − 6 III, ≐ 3 VIII − 9 III, by either of which last it may be tuned by perfect intervals. (*ę*)

DIERVILLA, a genus of plants of the class Pentandria, and order Monogynia. See Botany, p. 176.

DIET. See Aliments.

DIEU, Isle de. See Vendee La.

DIEUZE, a town of France, in the department of La Meurthe. It is situated on the river Seille, between Metz and Saverne, and has four convents and two hospitals. It is remarkable for its dyeworks, its manufactories of saltpetre, of hosiery and cotton goods, but particularly for its salt pits, which furnish annually 280,000 quintals of salt. The salt springs have existed since the beginning of the 11th century, and are the most considerable in Lorraine, both for their strength and copiousness. One hundred pounds of water furnishes 16 pounds of salt. The superfluous water is conducted by a canal to the salt-work of Moyenvic. The little river called the Spin, separates the salt works of Dieuze from the town. Population 3344. See Peuchet's *Dict. Commerçante*. Herbin *Statistique de France*; and Reichard's *Guide des Voyageurs en Europe*. (*j*)

DJEZAN Ras, Ghezan, or Gezan, is a seaport town of Arabia, in the principality of Abu Arisch, and the Province of Yemen. It is situated on the Red Sea, which forms one side of a large bay. The town is built with straw and mud, and carries on a considerable trade in senna, which grows in the adjacent country, and in coffee, which is brought from the mountains of Haschid-u-Bekil. The trade in coffee, however, has been in a great degree removed to Loheia and Hodeida. The town is well supplied with water, fruits, and excellent fish. It is particularly subject to fevers Its distance from Abu Arisch is about one day's journey. East Long. 42° 6′, and North Lat. 16° 53′, according to Lord Valentia's chart of the Red Sea. See Bruce's *Travels*, and Niebuhr's *Travels*. (*j*)

DIEZE, in Music, an interval, so called by Mr Edmund Stone, whose ratio is $\frac{24}{25}$, = 36 Σ + f + 3 m, or the SEMITONE *Minor*, which see.

DIEZE, DOUBLE MINIME, has a ratio $\frac{387,428,489}{400,000,000}$, or $\frac{3^{18}}{2^{10} \times 5^{8}}$, = 28.149661 Σ + f + 2m, or 28 Σ + 2 f + 2m; its log. = .9861225,9363. It is = 𝒻 + χ, = ∂ + r, = 3𝒻 — 𝕊, = 𝒻 + χ + Σ∂ + f + 2Σ, = 𝒻 + f + 3Σ, = 𝒻 + R — r, = 𝒻 + π — đ, = 𝒻 + P — 5c, = 𝒻 + 𝒮 — 3c, = 𝒻 + r — Σ, = ∂ + χ — Σ, = ∂ + L — 4 c, = ∂ + S — 5 c, = S + ∂ — 6 c, &c.

DIEZE MAJOR of Rameau, has a ratio $\frac{125}{128}$, = 21 Σ + 2 m, or the ENHARMONIC *Diesis*, which see.

DIEZE MAXIME of Rameau, has a ratio $\frac{243}{250}$, = 25 Σ + f + 2 m, or the SEMITONE *Subminimis*, which see.

DIEZE MINIME (D), an interval so named by M. Rameau, it being the remainder when the semitone minimum is taken from the limma. Its ratio is $\frac{19683}{20000}$, the component primes of which are $\frac{3^9}{2^5\ 5^4}$: its common log. is .9930612,9682, and its reciprocal log. .0069387,0318: in the Binary logarithms of Euler, or decimals of the octave, it is = .023054, in major comma logarithms 1.286130, and in schisma logs. = 14.157524. In Farey's notation, (see our article APOTOME, and Plate XXX. in Vol. II.), it is = 14 Σ + f + m, or when reduced to his regular increasing series, wherein negative signs are wholly avoided, either in the terms or the intervals between them, = 14.14966096 Σ + m.

In tuneable intervals, it is = 4-4ths — III — 5-3rds; and thus it may be tuned on an instrument like Mr Liston's, by ascending four perfect fourths, and from the upper note descending a major third and five minor thirds: none of the 59 notes on the euharmonic organ stand in this relation to each other, although four adjacent intervals thereon differ only a schisma in excess, being each C + f€ instead of € + f€. See the *Phil. Mag.* vol. xxxix. p. 419.

The equations which follow, expresssd in the symbols of Plate XXX. above referred to, will shew the exact relation of this interval to all the others in that Table, viz.

D = đ + r
= c + f€
= € + χ

D = R + 2f€
= φ + 4 Σ

D = L — 𝑓
= ∂ — đ
= π — Σ

D = 𝒻 — c
= 𝒮 — 2c
= 𝕊 — 3c
= P — 4c

D = 2 𝒻 — S
= 2𝒮 — P
= 4 𝕊 — 3P
= 3𝒮 — 2𝕊

D = Σ + c + r
= 2Σ + đ + f
= 3Σ + c + f
= 3Σ + R + R

D = 4 Σ + € + f
= 11Σ + χ + m
= 14Σ + f + m

D = 14 d + 43 f — 13m
= φ + f€ — f
= 15Σ + 2 m — F
= c + R — r

D = đ + R — χ
= π + r — χ
= 9Σ + m — f€
= S + Σ — 5 c

D = 𝒻 + Σ — đ
= π + c — đ
= ℰ + f€ — đ
= 𝒮 + χ — 𝒻
= 𝒻 + π — ∂
= S + π — P
= 𝕊 + 𝒻 — P
= L + ∂ — P
= S + f€ — P
= 2c + 2 𝒻 — P
= 6 c + 2 χ — P

D = 2€ + 2 ∂ — P
= 2ℰ + 2 π — P
= 6đ + 2 f — P
= T + χ — t
= 𝕋 + χ — T
= t + 𝒻 — 𝕋
= 2 t + 𝒮 — 2T
= 3 t + 𝕊 — 3T
= 4 t + P — 4T
= T + 𝒻 — 𝕋
= t + 𝒮 — 𝕋

D = 2 đ — R — 4 Σ
= 4 ℰ — 2R — P
= 𝒻 — € — Σ
= 3 𝒻 — χ — P
= 2L — 2€ — P
= 2𝕊 — 2 c — P
= 2 S — 2 𝑓 — P
= t — Ṡ — C

D = t — ℰ — P
= 2t — 2S — P
= 2t — 𝕋 — S
= 3t — 2T — S
= T — 𝑓 — P
= 2T — 𝕊 — P
= 𝕋 — 𝕊 — 3c

DIEZE MINOR of Rameau, has a ratio $\frac{3072}{3125}$ = 15 Σ + f + m, or the HYPEROCHE, which see (*ϱ*)

DIGITALIS, a genus of plants of the class Didynamia, and order Angiospermia. See BOTANY, p. 250.

DIGNE, DINIA, or DIGNA, is an ancient town of France, and principal place of the department of the Lower Alps. It is situated in a fertile valley at the foot of mountains, upon the left bank of the river Bleonne, which is still called *Mardoric*. The principal buildings in the town are the cathedral, five convents, a seminary, a college, and an hospital. This town, however, is chiefly celebrated for its mineral waters and warm baths which are at the distance of about a league. The temperature of the water varies from 30° to 40° of Reaumur. In cases of anchylosis, or stiffness of the joints, produced by gun-shot wounds, it has produced wonderful cures. The mountains in the neighbourhood abound in petrifactions, and the crater of an extinct volcano appears on one of the highest summits. There is here a manufacture of paper, of caps and stockings, and of drabs called kalmoucks; and great quantities of excellent fruits are collected in the adjacent valleys, and are exported to other parts of France, Italy, and Germany. Population of the town 2872. East Long. 6° 14′ 19″, and North Lat. 44° 5′ 18″. (*j*)

DIGYNIA. See BOTANY, p. 73.

DIJON, a town of France, formerly the capital of Burgundy, but now the chief place in the department of the Cote d'Or, and of the 6th cohort of the legion of honour. It is situated in an agreeable and fertile plain, between the rivers Ouche and Suzon, the first of which rises to the south of the town, while the last, which is frequently dry, flows past it on the north. The town is entered by five gates, viz. the Gate of Bourbon, the Gate of St Nicholas, the Gate of William, the Gate of Ouche, and the Gate of St Peter. It has three fauxbourgs, viz. those of St Peter's, of Ouche, and of St Nicholas, which communicated with the Chartreuse, before its destruction, by a long and fine avenue of large trees. The town is of an oval form, its length being 1500 paces, its breadth 1000, and its circumference, without including the suburbs, 1350 toises. The fine walls with which Dijon is surrounded, have half-moons, about 12 bastions, ditches, and a chateau in the form of a citadel. It is of a square shape, with a large round tower at each angle, and is flanked with two *fers a cheval*, one towards the town, and the other towards the country.

Streets and squares.

The streets of Dijon are straight, spacious, and well paved, and the houses are in general handsome and commodious. The Place Royale, now the Place Grande, was formerly decorated with an excellent equestrian statue, in bronze, of Louis XIV. by Le Hongrie, which weighed 52,000 pounds, and cost 108,000 livres, independent of the pedestal, which contained 1295 square feet of marble. The Place is constructed in the form of a horse-shoe, has a circular ballustrade, in the front of which is the magnificent provincial palace, called *Le Logis du Rois*, adorned with superb porticoes, and a very high tower, which has a fine effect. On the left hand is the *Palais des Etats*, and the street of Conde, (afterwards called the street of Equality), consisting of the most splendid houses, uniformly built; and on the right is the high and bold spire of St Chapelle, and the belfry of the cathedral, so as to render the view of the town from this place remarkably grand. The other squares are those of St Stephen, St John, St Michael, and that of the Cordeliers. The public buildings of Dijon are both numerous and elegant.

National Palace.

The Palais du Logis du Roi, now the *Palais National*, was formerly inhabited by the governors of the province, and has often been used by several of the French monarchs. It is surmounted by a large tower, which was begun in 1367, and finished by Philip-le-Bon. It is very high, and of an irregular shape, but has nevertheless a fine effect, and was employed as the observatory of the academy. In this palace, the 6th cohort of the Legion of Honour now hold their sittings. The inside of the square tower was formerly the kitchen of the Prince of Conde; the fire places for roasting are placed all around, with the stove in the middle to let out the smoke. It is now used, says M. Millin, for the preparation of soup a la Rumford. A few chambers of the ancient palace are all that remains.

Museum.

In one of the wings of this building is the museum of Dijon, which owes its establishment to the zeal of M. Desvoges, who first proposed it to the states of Burgundy. The room for study is large, and well suited to the purpose of drawing from engravings, busts, and models. In 1805, there were 150 students. Formerly they received prizes, and those who had this honour were sent to Rome. There are several rooms full of pictures, marble statues, and other curiosities. The room which contains engravings is very light, and is furnished with desks facing the windows: The number of engravings is 40,000. The rooms are open to the public every Sunday from twelve till two o'clock in winter, and from two till four in summer.

Parliament house.

The palace where the parliament of Dijon formerly assembled, is also worthy of attention. Its porch is adorned with columns and statues, particularly one of Henry II. in whose reign the great hall and the portal were begun. They were finished by Charles IV. The Hall of Public Audience was erected by Louis XII. The ceiling is extremely rich with gilding, sculpture, and painting. The painted glass which forms the windows, was a present from Francis I.

College.

The college of Dijon has always been reckoned one of the best regulated in France. Here are professorships of theology, philosophy, mathematics, the German language, history, rhetoric, eloquence, poetry, and humanity. Every three years, prizes, which were founded in 1737 by the first president, Jean de Berbisey, to the amount of 1000 livres, are regularly distributed. It has also a library and a physical cabinet.

Academy.

The academy of Dijon has been celebrated for having crowned an eloquent discourse of Rousseau's. It was founded in 1725, and has for its objects, morals, physics, medicine, belles lettres, and the arts. It holds its sittings in a magnificent saloon, adorned with the portraits of eminent men. An annual sum of 1800 livres was given by the states of the province to the academy, for the purpose of founding a public and gratuitous lecture on chemistry. Lectures are also given on materia medica, botany, philosophy, and anatomy. Attached to it is the botanic garden, situated a little to the east of the town. It was given to the academy by M. Legouz de Gerlan, who died in 1774. When the church of St Magdalen was demolished at the revolution, his remains were deposited in a black sarcophagus, and placed upon a base under the trees, at the extremity of the garden. Besides the botanic garden, this academy has a collection of natural history, a chemical laboratory, a medaillery, and an observatory.

Church of St Benigne.

The church of the abbey of St Benigne was consecrated in 535; but the present church was finished in 1288. It is reckoned one of the largest and most elegant in the kingdom, and deserves particular notice. The body of the church is 213 feet long over the walls, and 87 wide, 42 of which are occupied with the great nave, and it is 92 feet high under the roof. The spire, which is particularly admired, has only a small diameter, but rises to the height of 375 feet. The height of the cross is 36 feet, and the spire is furnished with a conductor. The front is ornamented with two similar towers, about 240 feet high, in one of which are two bells, one of 11 and the other of 15 thousand pounds weight. The organ is esteemed one of the finest in the kingdom. Behind the choir of this church are the ruins of a Pagan temple. It is an ancient rotunda, with three arches, one above the other, having a circular opening in the middle, and sustained by 104 columns, having their shafts of one stone. Nearly a third of this edifice is under ground.

Church of the holy chapel.

The collegiate church of St^e^ Chapelle, or the holy chapel, was founded by the dukes of Burgundy, in 1172. The body, which is of a moderate size, and of fine Gothic architecture, is about 167 feet long, 63½ feet wide without comprehending the collateral chapels, and 74 feet high under the roof. It is surmounted with a superb spire, about 350 feet high, reckoning from the pavement of the church. It contains a bell of alloyed silver, and the tower on the front has a fine chime of bells. The statues and paintings, and the miraculous host, which has been preserved in this church for several centuries, are the other objects in it which deserve notice.

Church of St Michael.

The church of St Michael is particularly remarkable for the richness and magnificence of its front, the principal features of which are two similar towers, formed of different orders of architecture, one above the other, and surmounted by two octagonal cupolas, terminated by balls of gilt brass. This building, is not of the Gothic style, like the other contemporaneous edifices, but is a striking example of good taste, at a time when the Greek architecture was despised. This church is 88 feet long over the walls, 89 wide, independent of the side chapels, and 64 high under the roof.

Church of St Stephen.

The church of St Stephen, now the cathedral church, was formerly an abbey, of the order of St Augustine.

Dijon. It was founded in the 12th century. In 1613, it was created into a collegiate church, and in 1731 it became the cathedral. It is 191 feet long, 56 wide, and 48 high under the roof. It is surmounted with a very fine belfry, covered with lead, and having a large bell and a chime; and the front of the church is of modern architecture, from the designs of a pupil of Mansard. It is adorned with a large bas relief of the famous Bouchardon, representing the martyrdom of St Stephen. This church contains several statues, paintings, and relics.

Church of St John. The collegiate church of St John is built in the form of a cross. It is 168 feet long, and as many broad. The spire, which is about 330 feet high above the pavement of the church, is greatly admired. The church is adorned with one large painting by Revel.

Church of Notre Dame. The church of Notre Dame is esteemed one of the most perfect models of Gothic architecture in Europe. It was built in the 13th century. The galleries are formed of small pillars of one piece, six inches in diameter, and from fifteen to thirty feet high. The roof is a piece of exquisite workmanship, and the front is truly magnificent. During the fury of the revolution, however, the statues in the pedentives were broken to pieces. M. Vauban was so struck with the perfection of this building, that he exclaimed that nothing was wanting but a box to preserve it in. The archives of the town are preserved in one of the towers, and upon the other tower, in the front of the church, is a clock with moving figures, which Philip the Bold, Duke of Burgundy, transported to Dijon, after the sack of Courtray.

The church of the Bernardines possesses a fine rotunda, terminated by a ball of gilt copper, and the principal altars are adorned with an excellent painting by J. B. Corneille.

Besides the churches which we have described, there are several others, and a great number of convents, which we cannot afford room to describe.

Chartreuse. The chartreuse, which was at the distance of a quarter of a league from the town, was founded in 1383. The monuments of Philip the Bold, of John the Fearless, and his Duchess Margaret of Bavaria, were of Parian marble, and were esteemed the finest productions of the arts. The figures reposed on superb tables of black marble, and at each tomb were two angels supporting the helmets of the dukes. Of these splendid monuments, a few mutilated fragments and figures only remain, to testify the loss which the arts sustained by the disorders of the revolution. The plough-share has now passed over a great part of the monastery which contained them.

The great hospital, called Notre Dame de la Charite, is deemed one of the finest establishments in France; ornament and utility being equally consulted by the architect. Besides this, there is the hospital of St Anne, and several other charitable institutions.

The promenades of Dijon are numerous and elegant. The ramparts, which encircle the city, afford more than an hour's walk, and command a view of the summit of Mont Blanc and Mont Gemni. The gardens of Montmusard, which are laid out in the English style, and the park which formerly belonged to the prince of Conde, are the most spacious. After the revolution, the city of Dijon purchased it for a public promenade, and laid it out in regular straight walks, from plans by Le Nostre. The river Ouche runs at one end of it. The Arquebuse, which was formerly the place of exercise for the cross-bow company, has been converted into an agreeable rural house of entertainment. It is a small house with a pleasant garden, planted in the English manner, and the ground floor forms a covered gallery, where the company can retire during rain.

Several fine pieces of antiquity have been found in Dijon. In the garden of the house of M. Richard de Veorottes, is a wall in which are preserved forty-two monuments of antiquity, which have been found in the city. In the middle of the wall is a black marble tablet, with the following inscription in letters of gold: Antiquities.

HÆC VETERUM MONUMENTORUM FRAGMENTA E RUDERIBUS PRIMÆVÆ URBIS DIVIONENSIS JUXTA TEMPLUM DIVI STEPHANI FELICITER ERUTA AD PUBLICAM UTILITATEM ET HORTORUM ORNAMENTUM ÆGIDIUS GERMANUS RICHARD DE RUFFEY IN SUPREMA RATIONUM BURGUNDIÆ CURIA PRÆSES EMERITUS SERVANDA CURAVIT. ANNO M.DCCLXXXI. An account of these monuments has been given by the celebrated antiquarian Millin, in the ninth chapter of his Travels.

The principal manufactures of Dijon are woollen stuffs, serges, calmouks, hosiery goods, playing cards, leather, pottery ware, wax candles, hats, and silk stockings. There is also a cotton manufactory, and an extensive nursery. Manufactures.

Dijon carries on a considerable trade in corn, cattle, and wine, which is sent to Paris, Strasbourg, Holland, and Switzerland, and it will be greatly facilitated by the new canal from St Jean de Losne to Dijon. It was unfinished in 1805, five sluices being wanting. It appears, however, to have been lately finished, and the branch from Dijon to St Florentin is now cutting. The fairs, which continue eight days, are held on the 10th March, the 10th June, and the 10th November. Population 22,000. East Long. 5° 2′ 5″, and North Lat. 47° 19′ 25″, by trigonometrical operations. See Montfaucon's *Antiquit. Expliq.* tom. iii. p. 240. for an engraving of the Diptic of Dijon, which is now in the museum; *Journal des Batimens et des Arts.* No. 110. and 112; Reichard's *Guide des Voyageurs en France*; Millin's *Travels through the Southern Departments of France,* chap. viii, ix; Lemaistre's *Travels,* vol. i; Herbin *Statistique de France*; and Tynna's *Almanac du Commerce,* pour 1811. DILATATION. See EXPANSION.

DILATRIS, a genus of plants of the class Triandria, and order Monogynia. See BOTANY, p. 96.

DILIVARIA, a genus of plants of the class Didynamia, and order Angiospermia. See Brown's *Prodrom. Plant. Nov. Holl. &c.* p. 480, and BOTANY, p. 259.

DILLENIA, a genus of plants of the class Polyandria, and order Polygynia. See BOTANY, p. 240.

DILLENIUS, JOHN JAMES, a distinguished botanist, in the early part of the eighteenth century, was born at Darmstadt, in Germany, in 1687. While prosecuting his medical studies at the University of Giessen, in Upper Hessia, he shewed his predilection for botanical pursuits. Of six communications which he presented to the Imperial German Academy, and which are printed in their *Miscellanea Curiosa,* no fewer than five treated of subjects connected with botany; and in 1719, he published, in octavo, a List of the Plants indigenous to the neighbourhood of Giessen, illustrated by some figures of his own engraving.

Sherard, the enlightened and liberal British consul at Smyrna, having recently before returned home, had his attention drawn towards Dillenius by the publication of this local Flora; and in 1721, prevailed on him to remove to England, and settle in London.

In this country Dillenius first brought himself into notice, by publishing an improved edition of the *Synopsis Stirpium* of the illustrious Ray. Here he discovered his partiality to the investigation of the tribes of minute plants, now known by the general title of Cryptogamia; particularly the Musci, which he first subdivided into the well-known genera Bryum, Hypnum, Minum, &c. He added twenty-four figures of rare plants, drawn and etched by himself. This edition of the Synopsis continued to be the principal guide to English botany, till the publication of Hudson's *Flora Anglica*; which again was in some measure superseded by Withering's *Arrangement*; while this last has been succeeded by Smith's *Flora Britannica*, a work the most perfect of its kind that has appeared in any country. The Dillenian edition of Ray's Synopsis, is still held in esteem by botanists, and has now become a very scarce book.

The consul Sherard already mentioned, who died in 1728, having left a considerable sum of money towards endowing a botanical professorship at Oxford, on condition that Dillenius should be the first professor; this appointment was accordingly carried into effect, and Dillenius was enabled to dedicate the rest of his life exclusively to botanical pursuits. The real object of the founder was the continuation of Caspar Bauhin's *Pinax*; a work in which he himself had laboured for some years. To this duty of the Sherardian professor, Linnæus long afterwards alluded, in dedicating to him his *Critica Botanica*; but the continuation of the Pinax, although understood to be in an advanced state of preparation, never was given to the public, owing entirely to the expence exceeding the means of Dillenius.

Dr Sherard, the brother of the consul, possessing an excellent botanic garden at Eltham, about eight miles from London, Dillenius, while resident in the capital, had been a frequent visitant; and had been led to undertake the describing and figuring of the plants in this collection. After many years labour, the *Hortus Elthamensis* came out in 1732, in two large volumes folio. In this splendid book, 417 plants are described and figured; and, as usual, the figures were not only drawn, but etched by Dillenius himself. While these engravings are certainly not to be compared with the matchless productions of Bauer and Hooker, in our days, they must be admitted to possess very great merit; and it was not without reason, that Linnæus pronounced the book, at the time of its publication, to be "*opus botanicum quo absolutius mundum non vidit.*"

In 1736, the Swedish naturalist paid a visit to Dillenius at Oxford. He was not able to persuade the Professor to renounce the method of Ray, and adopt his sexual system; but these great botanists agreed so well, that Dillenius was even desirous to associate Linnæus with him in his labours,—a plan, which, it is said, failed, through the opposition, or at least the indifference, of Sir Hans Sloane.

About this time, Dillenius assisted the learned orientalist Dr Shaw, in describing and figuring the new or rare plants which he had collected abroad; and the *Specimen Phytographiæ Africanæ*, subjoined to the Doctor's Travels in Barbary and the Levant, may be considered as the work of Dillenius.

For many years, Dillenius had attached himself principally to the investigation of the great family of the Mosses, including under this title not only the frondose mosses, but jungermanniæ, lichens, confervæ, byssi, and others. In 1741, he brought out, in one large volume 4to, illustrated with 85 plates, his *Historia Muscorum*. In this admirable work he describes and gives representations of about 600 species, many of them before unknown or undistinguished. By this treatise, the fame of Dillenius was firmly established. The perspicuity of his descriptions, and the general accuracy of his figures, have ensured him the praises of all succeeding botanical writers. Willdenow pronounces it an "incomparable work." When Linnæus afterwards published his System, he did little more, in the families of Mosses and Lichens, than arrange the Dillenian species, and reduce the copious specific characters into his own short and technical style. Both Dillenius and Linnæus, it may be remarked, were in the dark as to the nature of the fructification of the *musci frondosi*, which was first discovered by the celebrated Hedwig. But while Hedwig has illustrated the musci, and Acharius the lichens, the *Historia* of Dillenius continues to be a standard work of reference to this day. No more than 250 copies were printed; and yet so limited was the demand at first, that the author was a considerable loser by the publication. In less than thirty years, however, it became a rare book. In 1763, the plates were republished without the letter-press; and from this time a copy of the original edition, with the letter-press, bore the most extravagant price.

In 1811, a new edition of this splendid and expensive book was undertaken at the University press of Edinburgh, by Mr Charles Stewart,—a gentleman who has been long known as a keen naturalist, and as the author of an excellent elementary book, entitled, *Elements of Natural History*, published at Edinburgh in 1801. In order to save the original copy from being soiled in the course of reprinting, it was enclosed in a glass case, which was unlocked only when the compositor needed to turn a leaf. This new edition was printed page for page with the original, so that the references of authors might apply to it. No freedom whatever was taken with the original, except correcting some typographical errors which had escaped the author. Even the spelling of his English words was respected. To the synonymes given by Dillenius himself, Mr Stewart has very properly added, in an appendix, a list of modern synonymes. The plates were re-engraved with great care, the original plates having been destroyed many years ago. The whole work is in a style of elegance highly creditable to the Edinburgh press.

After his publication on Mosses, Dillenius, it is understood, turned his attention particularly to the illustration of English *fungi*, of many of which he prepared drawings and descriptions; but these he did not live to publish. He was of a corpulent habit, and was cut off by apoplexy in 1747, in his 60th year. A portrait of him is preserved at Oxford, but no tombstone marks his place of sepulture, the only monument to his memory being one strictly botanical,—the naming after him, by his friend Linnæus, of a genus (*Dillenia*), including several lofty and beautiful Asiatic trees. See Pulteney's *Sketches of the Progress of Botany*, vol. ii.; and *Biog. Brit. in loco*. (P. N.)

DILLINGEN, a town of Germany, in the kingdom of Bavaria. It was formerly in the circle of Suabia, and was the ordinary place of residence of the Prince Bishop of Augsburg, to whom it belonged.

It is situated on the Danube, and contains an episcopal palace, a Catholic university founded in 1552, a college of secular canons, a convent of capuchins, and two convents of religious. It is 12 miles north west of Augsburg. East Long. 10° 20′ 29″, and North Lat. 48° 34′ 17″, according to trigonometrical observations. (*j*)

DILLWYNIA, or ROTHIA, a genus of plants of the class Diadelphia, and order Decandria. See BOTANY, p. 286.

DIMERIA, a genus of plants of the class Triandria, and order Digynia. See Brown's *Prodromus Plant. Nov. Holl. et Ins. Van Diemen*, p. 204; and BOTANY, p. 116.

DIMINISHED INTERVALS, in Music, according to our nomenclature of this science, are any such intervals as are less than their true quantity, by the semi-tone minor or S, ($=36\Sigma+f+3m$,) and in like manner we call all intervals which are greater than their true quantity by S, *superfluous* intervals, whether the same are major or minor consonances, in either case. See the list of sixty notes on Mr Liston's organ, in the *Phil. Mag.* vol. xxxvii. p. 276. In speaking of regularly tempered scales, Dr R. Smith in his *Harmonics*, second edition, p. 165, says, "The interval of a minor consonance augmented by a minor limma, (*l*, see our articles DIESIS and LIMMA *of Tempered Scales*,) makes the interval of a *superfluous* consonance; and the interval of a minor consonance diminished by a minor limma, makes the interval of a *diminished* consonance."

If we examine Mr Liston's untempered or perfect diatonic scale of the octave C*c*, in p. 12, of his *Essay on perfect Intonation*, we shall find, that the *sharps* and the *flats* are in every case but one, applied to *major* intervals, (above C,) as I, II, III, &c.; and this exception occurs with F, the *minor* fourth or fourth of this key: this respects the giving of names to the notes or sounds. Mr Liston's restriction of ※'s to major intervals, and ♭'s to minor intervals, and so applying his terms *redundant*, (instead of *superfluous*,) and *diminished*, when treating of intervals generally in pages 115 and 137, however sufficient and well adapted the same may be to the purposes of the practical musician, seem wanting in that precision and method, which the subject is now capable of receiving in an elementary work.

If the term superfluous, (or redundant,) had been limited by Mr Liston to the quantity S, and also the term dimished to the same quantity, as has been mentioned above; and the marks ※ and ♭, when thus used to describe *intervals*, without reference to their place on the staff, or as marking particular *notes*, had also been restricted to S; and when such *intervals* required to be named or marked, as occur upon C, E, and A, and below E♭ and A♭, vulgarly called their sharps and flats, (see *Phil. Mag.* vol. xxxix. p. 275,) but which are, in reality, each equal to the semi-tone medius 𝕊, ($47\Sigma+f+4m$,) or S+*c* instead of S, the same had been called *acute-superfluous*, and marked ※', and *grave-diminished*, and marked ♭', a very considerable improvement would have been made in this truly valuable Essay, by avoiding all ambiguity. In tempered scales these distinctions do not apply, and ※$=l$, and ♭$=l$, in all cases, as Dr Smith remarks above: but for perfect instruments, and even for voices, C※', E※', and A※' and E♭♭', and A♭♭' had better be marked at the beginning of the staff, and wherever ※ and ♭ occur to these notes respectively; and then ※ and ♭ would, in every case, denote the interval S, or minor semitone. But at any rate, when treating of *intervals* and chords, without reference to the particular *notes* which form them, these distinctions ought not in future to be omitted, and ※ and ♭ sometimes be used to signify S, and sometimes 𝕊, as Mr Liston has unfortunately done, instead of writing ※'I, ※'III, and ※'VI; and ♭'3, and ♭'6; or he should have abstained altogether from the use of the marks ※ and ♭, when not used with reference to those at the cliff, (as observed by him at page 49,) and have used some other marks, attached to the numerals of the intervals, correctly defining the distinction between S and 𝕊, in the cases above referred to.

The analogy with the terms *major* and *minor*, to which Mr Liston refers in p. 137, in excuse for the ambiguity above complained of, cannot avail; for although practical musicians often say, "a flat third," and in works on thorough bass, &c. write ♭3 and ♭6, when they mean the minor third and minor sixth, and "sharp third" and "sharp sixth," when they mean the major third and major sixth, &c.; yet what theoretic writer, or indeed any other, writes ♭III for 3rd ($=161\Sigma+3f+14m$), or ※3rd for III ($=197\Sigma+4f+17m$), or ♭VI for 6th ($=415\Sigma+8f+36m$), or ※6 for VI ($=451\Sigma+9f+39m$), &c.: and yet we may tolerate and safely use E♭ and A♭ to designate the notes answering to the 3rd and the 6th of the key C, &c. as mere *names for these notes*, and without reference to their exact distance from any others in the scale, although we consider these notes, the 3rd and 6th and others, as equally *determined by nature*, and their place in the scale fixed with the same mathematical accuracy as the III. and VI. from which certain writers, during the infancy of the science, as to correct theory, happened to derive the former, and to name them accordingly: but in speaking of *the intervals between notes*, terms and marks that are definite and unvarying in their meaning, ought alone to be tolerated or used by theoretic writers of the present day, when mathematical accuracy can and ought to be given to every expression relating to musical intervals, as we are taking so much pains to shew in this department of our work.

Mr Maxwell, in his "*Essay upon Tune*," p. 51, &c. contends for and uses the words and marks sharp and flat and ※ and ♭, in one invariable sense as to magnitude, but he unfortunately fixed on 𝕊 ($=47\Sigma+f+4m$) for the same, instead of 𝒮 ($=36\Sigma+f+3m$), although the former occurs in practice only half as frequently as the latter. See *Phil. Mag.* vol. xxxix. p. 375.

We shall mention below, the intervals in alphabetical order, major and minor, to which we have seen the term *diminished* prefixed, using the numerals and symbols of our XXXth Plate, Vol. II. but omitting the cols. f and m, in order to shorten the detail; and only mention the Σ s, which then are the *artificial commas* of Farey, viz.

DIMINISHED *Eighth*, major, VIII—$\mathcal{S}=576\Sigma$; minor, 8—$\mathcal{S}=529\Sigma$.

DIMINISHED *Fifth*, major, V—$\mathbb{S}=311\Sigma$, and V—$\mathcal{S}=322\Sigma$; minor, 5—$\mathcal{S}=322\Sigma$.

DIMINISHED *Fourth*, major, IV—$\mathcal{S}=265\Sigma$; minor, 4—$\mathbb{S}=207\Sigma$, 4—$\mathcal{S}=218\Sigma$.

DIMINISHED *Fourth* of Bemitzrieder, has a ratio $\frac{6561}{8192}$, $=196\Sigma+4f+17m$, and its log. =.9035800,9412; the true minor fourth exceeds this interval by the apotome, or it is 4—P. See FOURTH *Minor*.

DIMINISHED *Second*, major, II—$\mathbb{S}=57\Sigma$, and II—$\mathcal{S}=68\Sigma$; minor, 2—$\mathbb{S}=10\Sigma$, and 2—$\mathcal{S}=21\Sigma$.

DIMINISHED *Seventh*, major, VII—$\mathcal{S}=519\Sigma$; minor, 7—$\mathbb{S}=461\Sigma$, and 7—$\mathcal{S}=472\Sigma$.

DIMINISHED *Seventh* of Calcott and Marsh, and greater diminished seventh of Chambers; it is equal to three minor thirds, has a ratio $\frac{125}{216}$, $=483\Sigma+9f+42m$, and its log. =.7624562,6185: the true minor seventh exceeds this interval by the semitone subminimis, or it is 7—f, or 7'—$\mathcal{S}$. But it seems probable, from comparing pages 164 and 202 of Dr Calcott's *Musical Grammar*, 1st edition, that in the latter page the Doctor has omitted the word "extreme," or "double," before

Diminished Intervals ‖ Dinant.

diminished, (see EXTREME *Diminished Intervals*), and that he intended to compare this interval 3-3rds, with the major seventh, because it is equal to $VII-2\mathcal{S}$, or the double diminished major seventh. See SEVENTH.

DIMINISHED *Sixth*, major, $VI-\mathcal{S}=415\Sigma$; minor, $6-\mathfrak{S}=368\Sigma$, and $6-\mathcal{S}=379\Sigma$.

DIMINISHED *Third*, major, $III-\mathcal{S}=161\Sigma$; minor $3-\mathfrak{S}=114\Sigma$, and $3-\mathcal{S}=125\Sigma$.

DIMINISHED *Third* of Bemitzrieder, or the double limma, (2 L) has a ratio $\frac{59049}{65536}$, $=92\Sigma+2f+8m$, and its log. $=.9547326,1658$: the true minor third exceeds this interval by $69\Sigma+f+6m$, or $2L=3-\mathfrak{S}-\Sigma$.

Dinapore ‖ Dingle.

DIMINISHED *Seventh, Chord of*, consists, according to Mr Liston's *Essay on perfect Intonation*, p. 90, of three minor thirds, the middlemost of which is grave, or a common deficient minor third, and this chord is thus represented by him in numerals, and by us in artificial commas, viz.

♭7		472		VI		451		VI′		462		VI		451
5	or	311,	and its inversions are	5	or	311,	or	IV	or	301,	and	IV	or	301.
3		161		3′		150		3		161		※II		140

DIMINISHED, *Double or Extreme, Intervals*, are such as are lessened two minor semitones, or $2\mathcal{S}$ $(=72\Sigma+2f+6m)$, according to our nomenclature; but it is not uncommon to meet in musical writings with intervals so called, which are lessened a minor and a medius semitone, or $\mathcal{S}+\mathfrak{S}$ $(=83\Sigma+2f+7m)$. See EXTREME *Diminished Intervals*. (ϱ)

DIMOCARPUS, a genus of plants of the class Octandria, and order Monogynia. See BOTANY, p. 199.

DIMON, Greater and Lesser. See FAROE ISLES.

DIMORPHA, a genus of plants of the class Diadelphia, and order Decandria. See BOTANY, p. 281.

DINAN, a town of France, in the department of the Cotes du Nord, and chief place of the arrondissement of the same name. It is situated near the left bank of the river Rance, and has a small harbour, and a communication with St Malo. It has a fine chateau, two convents, and an excellent hospital. Several manufactures are carried on in Dinan, the principal of which are those of linen cloths, flannel, drabs, ribbands, and leather. Twelve thousand pieces, of 100 ells each, of linen cloth, were manufactured annually.

This town, however, is chiefly celebrated for its mineral waters, which are much frequented by strangers. According to the experiments of M. Monnet, who analyzed the water in 1769, it contains carbonate of iron, and muriate of soda. Its taste is ferruginous. Though pellucid when it issues from the spring, yet if left exposed to the air, it becomes turbid, and deposits an ochreous sediment at the bottom of the vessel. It then loses its metallic taste, and becomes insipid. It acts as an aperient, a detergent, an astringent, and a tonic; and is particularly recommended in cases of deficient or superabundant menstruation. There is a society of agriculture at Dinan, and the surrounding country produces abundance of corn, hemp, and flax. A considerable trade is carried on in butter, flax, honey, and tallow. A fair, called *Le Liege*, is held on the second Tuesday of Lent. It lasts eight days, and there are sold at it horses, cattle, jewellery, and haberdashery goods. Population 4200. West. Long. 1° 59′, North Lat. 48° 27′ 16″. (*j*)

DINANT, a town of France, in the department of the Sambre and the Meuse, and chief place of the arrondissement of the same name. It is situated on the right bank of the Meuse, between a steep rock and the river. The chief buildings are a collegiate church, and seven other churches which are annexed to it; a college, six convents, and two hospitals. It had formerly a castle, and was well fortified, but the fortifications were demolished in 1703. Dinant has long been celebrated for its manufacture of braziery goods, which have received the name of *Dinanderie*, of which considerable quantities are sent to almost every part of Europe. Its tanners are also famous, and many skins are exported. It has also manufactories of cards and paper, and a refinery of sugar. In the neighbourhood are veins of black, white, and red marble, and other stones, out of which works and utensils of all kinds are continually sent to Holland and Westphalia. There are likewise rich mines of iron in the neighbourhood. Population 2964. (*j*)

DINAPORE, a town of Hindostan, in the district of Patna and province of Bahar, remarkable for the elegant and magnificent military cantonment erected by the East India Company. The accommodation enjoyed by the officers and soldiers is much more extensive than in the best English barracks, and the apartments are spacious and well-aired. The troops belonging to the native battalions are lodged in small tents, a little inferior to those of the natives. Bread, and every article of food, is here remarkably cheap. See Tennant's *Indian Recreations*, vol. ii. (*j*)

DINAS-MOWDDWY, or DINASMOWTHY, is a village of North Wales, in the county of Monmouth, placed at the junction of three vallies on the shelf of a precipice, called Craig-y-Dinas. It is delightfully situated near the small river Cerris, at its junction with the Dovey or Dyfi. The road winds circularly round the declivity of the mountain; and as the streets have a similar curve, the village appears from a distance as if suspended on the side of a mountain. The buildings are mud cottages, one story high, and covered with rushes. There is a good bridge over the river, and the church is more than a mile from the village.

This place was formerly of considerable consequence. It was a fortified city, and the residence of a chieftain, and possessed very extensive privileges, till the reign of Henry VIII. when the laws of England were extended to Wales. The corporation consists of a mayor, alderman, recorder, and several burgesses. The mayor possesses the right of trying criminals, though he has not exercised this privilege for several years. The mayor and aldermen are justices of the peace within their little district, and they have the exclusive power of granting licences to victuallers. In the absence of the lord of the manor, the recorder hears and determines causes of debt not exceeding forty shillings sterling.

The number of houses in this village and the parish of Llan Mowddy, is 45, and the number of inhabitants about 225. There are three annual fairs in the village, and well supplied markets on Friday. See Pennant's *Tour in Wales*, vol.ii.; Evans' *Tour through North Wales*; and Evans' *Beauties of England and Wales*, vol.xvii. p. 919. (*j*)

DINGLE, or DINGLE-I-COUCH, a market and post town of Ireland, in the county of Kerry. It is situated on the north side of Castlemain Bay, and has a harbour about a quarter of a mile broad at its mouth, but wider within, so as to shelter ships from all winds. Vessels of 100 tons can come up to the town. Many of the houses are built in the Spanish style, with ranges of stone balcony windows, owing to several Spanish merchants having resided here before the time of Queen Elizabeth. In the neighbourhood of Dingle, a strong linen fabric is made under the name of *box* and *trap*. "Towards Dingle," says Mr Wakefield, "the linen manufactured is 3-4ths wide, and sells for 1s. and 1d. per yard. Every family of all classes sow their own flax. In gentlemen's houses, the women servants spin it, and it is given out to be wove. Except table linen, every thing is manufactured at home." This town exports butter and other articles of provisions. It was once a borough, but lost its privileges at the union. See Smith's *Account of Kerry;* and Wakefield's *Acccount of Ireland, Statistical and Political,* vol. i. p. 690. (π)

DINGWALL. See Ross-Shire.

DINKELSBUHL, or Dunkelsbuhl, Tricollis, Zeacollis, or Zeapolis, is an ancient town of Germany, situated on three hills upon the river Wernitz. It was once a free and imperial city, but at the treaty of Luneville it was given to Bavaria as a part of her indemnities, for what she ceded on the Western bank of the Rhine. The chief altar of the church of the Carmes is adorned with a very fine painting. The principal manufactures are those of woollen goods, shoes, hats, stockings, fustians, and beer. The cheese of this town is much admired. The inhabitants, half of whom are Lutherans and the other half Catholics, amount to 6500. (*j*)

DINKIRA, a country of Africa in the interior of the Gold Coast. It is distant about 10 days journey from Axim on the coast, and about 5 from Mina or Elmina. It is bounded by Kabesterra on the east, Adom on the west, and Achen on the north. The roads from Axim and Mina are extremely bad, though with very little labour they might be greatly improved and shortened. The Dinkirese are said to have much gold, which they obtain partly from their own mines, partly by pillage, but chiefly from commerce, which they understand better than the other negroes. When the roads are open, the Dinkirese and the Achenese merchants frequent the markets of Schama, Axim, Commendo, Mina, and Cape Coast; but when the roads are shut up, they go to the more distant parts of the coast. The gold of this district is very fine, but is often mixed with the gold of Fetiche. (*j*)

DIOCLESIAN, or Diocletian, the forty-second emperor of Rome, was born A. D. 245, at Doclea or Dioclea, in the country of Dalmatia; and, from the place of his nativity, he bore originally the name of Diocles, which he afterwards extended, by a Roman termination, into Dioclesianus. His father was at one time a slave, but afterwards obtained his freedom, and appears to have raised himself at length to the office of a notary or scribe. Dioclesian entered the army at an early age, and, while he yet held the station only of a common soldier, had his ambition remarkably excited by the speech of a druidess at Tongres, in France, in whose house he chanced to lodge; and who, in settling his daily charges, was provoked, on one occasion, by his miserly disposition, to reproach him with covetousness. "As a poor soldier," he replied, "I must exercise œconomy; but I shall be more generous when I am emperor." "Do not," said the druidess, "treat these words as a joke; for, assuredly, you shall become emperor, after having slain a wild boar." From that moment he conceived the most aspiring hopes, and secretly imparted his expectations to his friend Maximian. Mindful of the prediction of his hostess, he was perpetually aiming at its accomplishment, by seizing every opportunity, in hunting and putting to death wild boars with his own hand; and, as he saw the imperial authority passing successively through the hands of Aurelian, Tacitus, Probus, Carus, and Numerian, he used to say sportingly to his friend, "I always kill the boars, but others eat the venison." He pursued, however, a surer road to the attainment of his object, by studying to excel in the military art; and soon became so eminent in his profession, as to be generally ranked among the number of excellent commanders, who were formed under the discipline of Probus. He distinguished himself so much in the expedition of Carus against the Persians; that he was promoted to the consulship, and, at the time of Numerian's death, he held the command of the imperial guards. This was a station, from which more than one of his predecessors had stepped into the throne; and, as soon as the death of Numerian was known, he was unanimously proclaimed emperor, by the army, at Chalcedon, A. D. 284. Instantly ascending the tribunal, he solemnly assured the soldiers with an oath, that he was in no respect accessory to the removal of their late sovereign; summoned the actual murderer Arrius Aper into his presence; and, charging him with the atrocity of his crime, plunged his sword into his breast. To this summary punishment of the assassin, with his own hand, he is supposed to have been impelled by a desire to fulfil the words of the druidess; and is said to have exclaimed, upon beholding Aper fall, "Now, at last, I have killed the fatal boar!" * After making his public entry into Nicomedia, in the character of emperor, he prepared to meet Carinus, the brother of Numerian, who was advancing from Gaul, with a powerful army to contest the succession. Several bloody battles were fought in Illyricum, between these two competitors, in one of which, in Upper Mœsia, Dioclesian was entirely defeated; but Carinus, who was detested for his debaucheries, was slain while pursuing his adversary, by a tribune of his own army, whose wife he had seduced; or, as Eutropius relates, was betrayed by his soldiers, and put to death by the command of Dioclesian. Being now sole master of the empire, he marched to Rome, for the purpose of establishing his authority; and completely gained the esteem of his subjects, by the generosity which he displayed towards those who had supported Carinus, and by the purpose which he professed of making the emperor Antoninus his model. He soon after set out for Germany, where he gained some advantages over the Allemanni; and his generals in Britain having likewise proved successful, in the field, he assumed, upon these grounds, the surnames of Germanicus and Britannicus. Being threatened, however, by several pretenders in Gaul, and having in his own disposition a greater portion of the statesman than of the warrior, he began to experience the want of a more warlike assistant; and, as he had no male issue, for whom he might have wished to secure the succession, he chose as his associate in the empire, A. D. 286, Marcus Aurelius Valerius Maximian, whose personal attachment he had long and fully experienced, and who united the most undaunted courage, with the most eminent military talents. Reserving to himself the eastern

* The word *Aper* signifies a *wild boar.*

provinces, he allotted to his colleague the more western countries, Italy, Africa, and Spain. He assumed also the title of Jovius, while Maximian took that of Herculeus; and they continued to preserve, upon the throne, the same steady friendship which they had long cherished in a private station. His more warlike associate respected the superior intellect of his patron, who knew well, on his part, how to employ the stern bravery of the other, as a ready instrument in executing the severer measures of government. Proceeding to their respective regions, Dioclesian, by the mere terror of his preparations, compelled the Persian king to restore Mesopotamia, which he had wrested by surprise from the empire; and gained various successes over the Saracens and Goths, in Pannonia. Maximian, in the west, was not less prosperous, routing the Germans and other barbarous nations, wherever they ventured to wait his approach. For these successes they obtained a triumph, and afterwards proceeded in different directions, in the depth of winter, to hold a friendly conference at Milan, A. D. 290; a meeting, it is conjectured, which had no other object than merely to manifest the cordial union which subsisted between them, and thus indirectly to secure the tranquillity of their dominions. Two years after this event, they found sufficient occasion for all their united wisdom and courage; and were barely competent to preserve the empire amidst the host of enemies, both foreign and domestic, by whom it was assailed. Carausius, a famous sea captain, still held the sway in Britain, of which he had taken possession several years before. The Persian king broke into Mesopotamia, threatening to overrun all Syria; while five confederated nations were desolating the provinces of Africa. Aurelius Julianus had caused himself to be proclaimed emperor in Italy; and Achilleus assumed the same title in Egypt. In order to make head against these accumulating dangers, the two emperors formed the resolution of choosing two approved generals, who should bear the title of Cæsar, and succeed them in the administration of the empire. In this view, Dioclesian made choice of Galerius, who was surnamed Armentarius from his original occupation of a herdsman; and Maximian selected Constantius, whose pale complexion had procured him the appellation of Chlorus. That this union of power might be cemented as firmly as possible, the two elected princes were obliged to enter into an alliance with the imperial families, Galerius espousing Valeria the daughter of Dioclesian, and Constantius taking to wife Theodora, daughter-in-law of Maximian. A new division of the empire followed this arrangement. Dioclesian chose for himself the rich countries of Asia to the east of the Egean Sea; and allotted to Galerius the regions of Thrace and Illyricum. Maximian held Italy and Africa, with the adjoining islands; and Constantius was charged with the defence of Gaul, Britain, and Spain. Each of them reigned as an absolute sovereign in his respective district, but all harmoniously concurred in the enactment of laws, applicable to the whole empire, and always paid great deference to Dioclesian, as their common father and benefactor. Many inconveniences, however, attended this plurality of sovereigns, especially the multiplicity of civil and military offices, which were necessarily required by four distinct courts; and the additional load of taxes for their support, which reduced many provinces of the empire to the greatest misery.

Dioclesian, thus supported by new associates, proceeded to Egypt, where Achilleus had usurped the sovereignty; and having compelled him, after a siege of eight months, to surrender the city of Alexandria, he exercised the most cruel vengeance upon the inhabitants, and also upon those of Busiris, Coptus, and the other principal Egyptian towns. Hence he passed to Antioch, A. D. 296, in order to superintend the operations of the Roman army against the Persians; but committed the execution of his plans to Galerius, whom he had recalled from Illyricum for that purpose. The temerity of this prince subjected him to a severe defeat from the king of Persia; and, when he returned to report his ill success to Dioclesian, he experienced a cold and contemptuous reception, being allowed to follow the emperor's chariot several miles on foot, before he was indulged with an audience. But, when Dioclesian had thus displayed his superior authority, and Galerius had shewn his eagerness to retrieve his lost honour, he was again intrusted with an army of 25,000 men, with which he gained a decisive victory over the Persian monarch, and secured a peace of the most advantageous terms for the empire. His success completely re-established in that quarter the glory of the Roman name; but was attended with fatal consequences to Dioclesian himself. Galerius, elated with his conquests, assumed the pompous titles of Persicus, Armenicus, Medicus, Adiabenicus, and even styled himself the son of Mars. In this boastful disposition, he could not easily brook the thought of a superior; and, by his haughty demeanour, began to prepare Dioclesian for his future usurpations. That emperor, in the meantime, was busily occupied by the internal arrangements of the empire, and by the fortifications of its frontiers along the Euphrates, the Danube, and the Rhine. He spent the winter of the year 302 at Nicomedia, together with Galerius, whose ascendancy was daily increasing, and who was at this time keenly employing all his influence with his colleague, to procure the extermination of the Christians. Dioclesian himself, though much attached to the Heathen superstitions, did not entertain any aversion to the Christians; and had many of them among the officers both of his court and army. Galerius, on the contrary, had imbibed, from his infancy, the bitterest enmity against them, and was himself utterly ignorant of every subject, except military affairs. Influenced by the suggestions of his superstitious mother, the insinuations of the Pagan priests, and the ferocity of his own natural disposition, he solicited Dioclesian, with the most urgent importunity, to adopt the most violent proceedings against his Christian subjects. The emperor, much inclined to cement measures, consented to exclude all who professed that religion from every civil and military office, but was reluctant to shed blood. Galerius, however, at length prevailed; and, on the 23d of February 303, an order was issued to pull down the churches of the Christians, to confiscate their ecclesiastical property, to burn their sacred books and other writings, to render them incapable of holding any honour or employment in the state, and to exclude the whole mass from all the privileges of subjects, and protection of the law. Although this edict did not directly affect their lives, yet many of them, in consequence of refusing to surrender their sacred books to the magistrate, were punished with death. Soon after the publication of this edict, the palace of Nicomedia, in which both the emperors then lodged, was twice discovered to be in flames, and part of the building was reduced to ashes. This accident is ascribed by Constantius, who was upon the spot, to the effects of lightning; but Lactantius affirms, that it was done by the secret orders of Galerius, that he might find an accusation against the Christians.

To their account, whoever was the author, it was charged by that Prince; who, at the same time, took his departure from Nicomedia, declaring his dread of being burnt by their machinations. The timid and credulous Dioclesian, doubly exasperated by his terrors, let loose all the fury of his vengeance against his Christian subjects; commanded numbers of them to be put to death in the most inhuman manner, as incendiaries; and issued a second edict, ordering all their bishops and teachers to be cast into prison. A third edict speedily followed, directing every species of punishment and torture to be inflicted upon these unhappy captives, in order to compel them to join in the sacrifices of the Heathen deities, that by their example their respective congregations might be influenced to renounce their religion. In consequence of this barbarous mandate, multitudes of the most eminent and virtuous characters in every quarter of the empire, (excepting Britain and Gaul, where Constantius Chlorus befriended the Christians,) were put to death by inexpressible tortures, while others were sent to the mines to drag out the remainder of their days in the most humiliating servitude. In 304, a fourth edict was issued, at the instigation of Galerius, which required the magistrates to compel every Christian of every rank and sex, to offer sacrifice to the Heathen gods, and to employ every kind and degree of torture for this purpose. This persecution, which is generally reckoned the tenth, and which was much more bloody than any which had preceded it, continued to rage, with little abatement, for the space of ten years, when Galerius at length, suffering, in his turn, from the horrors of a mortal and excruciating disease, recalled these barbarous decrees, A. D. 311, and restored repose to the wretched remains of his Christian subjects. It had very nearly, indeed, proved fatal to the Christian name; and at one period of its progress, the tyrants themselves boasted, in a public proclamation, that they had extinguished that powerful superstition, and restored the worship of the gods to its former splendour.

From the commencement of this persecution, the Emperor Dioclesian, to whatever cause it may be ascribed, was pursued by a succession of calamities. After celebrating a magnificent triumph at Rome, A. D. 303, on account of the success of his arms, and his entrance into the twenty-third year of his reign, he retired to Nicomedia, with the design of prosecuting his embellishments of that favourite city. Here he was seized with a lingering disorder, which reduced him to a state of extreme debility, terminating in a species of epilepsy; and when he appeared again in public, about the beginning of the year 305, in order to dissipate the reports which were propagated of his death, he was so pale and emaciated, that he could scarcely be recognized by those who had been most familiarly acquainted with his person. Galerius, about the same time, returned to Nicomedia, requiring him to resign the imperial authority, as he was now become unfit to discharge its functions, and threatening to compel him by force, should he refuse to make a voluntary surrender of his power. It has been alleged, that such was in fact the private intention of Dioclesian, in consequence of his feeble state of health; but it is an unquestionable fact, that the execution at least of his purpose was hastened by the demands of his ambitious colleague, who had in like manner intimidated Maximian to retire at the same time from the sovereignty. On the same day, therefore, the first of May 305, Maximian at Milan, and Dioclesian at Nicomedia, publicly abdicated the imperial throne; and the latter immediately withdrew to a favourite residence in his native country of Dalmatia, near to the city of Salona. Here he built a magnificent palace, of which some remains are still to be seen, and which form a part of the modern town of Spalatro. In this retreat he amused himself with the operations of planting and gardening, in which he used to declare, that he enjoyed more happiness, than when he was adorned with the purple; and was often heard to exclaim, "Now it is that I live; now I see the beauty of the sun!" When Maximian afterwards solicited him to resume with him the reins of government, he is reported to have made the following reply: "I wish that you could come to Salona, that I might shew you the pot-herbs, which I have planted with my own hand, and I am sure that you would never again make mention to me of the empire." Though he was at first greatly honoured in his retirement, by his successors, yet he experienced many afflicting, or at least humiliating circumstances, both in his own condition, and in the treatment of his family. His wife Prisle, and his daughter Valeria, were both treated with the utmost severity by Maximian, and finally banished to the deserts of Syria, in spite of all his solicitations in their behalf; while he himself received some threatening messages from Constantine and Licinius, who had suspected him of being engaged in the disturbances occasioned by Maxentius. He was thus constantly in dread of suffering an ignominious death; and this apprehension, united with his distemper, threw him into such an agitation of mind and body, that he enjoyed no rest, either night or day, but spent his whole time in sighs and tears. At last, worn out by his suffering, or, according to others, having poisoned or starved himself, he expired in the 68th year of his age, A. D. 313. A magnificent tomb was erected to his memory, and he was deified with the usual solemnities.

It has been noticed as rather an unaccountable circumstance, that, though no reign was more remarkable for its length and its events, and though a great number of historians flourished during its course, yet there is none of the Roman emperors, whose history is more imperfectly known than that of Dioclesian. This has been ascribed by some writers to the hatred which the Christians bore to his memory, which led them to suppress all histories and memoirs of which he was the subject; and by others it has been considered as the just retribution of Heaven, for his endeavours to abolish the sacred records. It is generally admitted, that he was desirous of emulating good emperors, and diligent in promoting the welfare of the empire. He enacted many excellent laws, and studied particularly to render provisions abundant in his army, his capital, and in every quarter of the empire. He discountenanced vice, promoted virtuous characters to places of trust, and, until seduced by Galerius, was rather a friend than an enemy to the Christians. But he may be regarded as one who acted a part, and was naturally devoid of those qualities which constitute an amiable or estimable prince. Not to mention his barbarous persecution of the Christians, his general mode of government tended to the oppression of the people. He degraded the character of the senate, altered the very titles of the magistrates, and changed entirely the Roman system. His whole establishment was formed upon a principle of ostentation; and he imitated, in every thing, the stately magnificence of the eastern potentates. He assumed the diadem, which the Romans detested; and arrayed his person in the most sumptuous attire of silk and gold. He instituted a variety of forms at court, which precluded access to his throne, and entrusted the care of his palace to the vigilance of eunuchs; required every subject, even of the highest rank, when at length introduced into his presence, to fall prostrate to the ground, and to approach him as a divinity; ordained them even, it is said, to kiss his feet, and had his shoes, for the purpose of this ceremony, embroidered with gold, and studded with precious stones. He multiplied offices and magistrates not only in his own immediate service, but in every department of the state; a circumstance which produced an increase of the taxes, and tended to impoverish his subjects. He was wonderfully addicted to building, and embellished many of the principal cities with magnificent edifices. At Nicomedia, in particular, he indulged this passion to an extravagant and pernicious extent, erecting a mint, an arsenal, a circus, a palace for his wife, another for his daughter, and several royal residences for himself, obliging many of the citizens to abandon their habitations, in order to make room for these structures, and exhausting the finances of those that remained, by the expences of materials, workmen, and beasts of burden. Nor did he hesitate to pull down the most costly buildings, again and again, when they failed to please his fancy, and to cause them to be rebuilt upon a different plan. His baths, at Rome, were particularly remarkable for their magnificence and extent, being capable of accommodating 3,000 persons, and having more the appearance of a city than of a single edifice. His personal character was that of an experienced politician, without the presence of any shining abilities or estimable moral qualities. He was skilful in the direction of public business, and thoroughly versed in the knowledge of mankind; dexterous in conceiving his schemes, and steady in the pursuit of his ends, even while he prudently varied his means; capable of profound dissimulation, with all the appearance of military frankness; naturally inclined to violent measures, but at the same time master of his temper, and completely able to submit all his passions to the aims of his ambition, which he knew also how to invest with the semblance of justice and of public utility. He was well acquainted with the military art, but not very apt to expose his own person to danger; inclined to avarice, and bent upon amassing wealth, which he frequently procured by acts of cruelty. He was universally noted for pride and arrogance, generally suspicious and distrustful; while, at the same time, none of those whom he called his friends, could ever discover that sincerity of affection on his part, which would fully justify confidence on theirs. See *Ancient Univ. Hist.* vol. xv. p. 483; Gibbon's *Rom. Hist.* vol. ii.; Crevier's *Rom. Emp.* vol. ix. x.; Mosheim's *Eccles. Hist.* vol. i.; and Esprinchard's *Histoire Auguste*, p. 497. (*q*)

DIODIA, a genus of plants of the class Tetrandria, and order Monogynia. See BOTANY, p. 123.

DIOGENES, a celebrated Grecian philosopher of the sect called Cynics, was born at Sinope, a city of Pontus, in the third year of the 91st Olympiad, or 414 B. C. His father, Icetas, was a banker, who, being convicted of debasing the public coin, was banished from his native city. From thence he removed to Athens, where Diogenes offered himself as a pupil to Antisthenes, the founder of the Cynic sect, who at first peevishly refused to admit him. Diogenes still continuing to importune him, the surly philosopher lifted up his staff to drive him away, upon which the young student exclaimed, "Beat me as you please, I will still be your scholar!" Antisthenes at length consented to admit him; and he afterwards became his intimate friend and companion. From that period, Diogenes adopted the opinions and principles, and conformed to the austere habits of his master; distinguishing himself, upon all occasions, by a thorough contempt of riches and worldly honours, and an excessive indignation against every species of luxury. He wore a coarse cloak, carried a wallet and a staff, made the porticoes and other public places his habitation, and, like a common mendicant, sought a scanty and precarious subsistence in the casual contributions of charity. Having been disappointed in his endeavours to procure a cell, he is said to have taken up his abode in a cask, tub, or large open vessel, in the *Metroum*. This circumstance is alluded to by Juvenal, Sat. xiv. v. 308.

> " *Dolia nudi*
> *Non ardent Cynici; si fregeris, altera fiet*
> *Cras domus, aut eadem, plumbo commissa, manebit.*

> " The naked Cynic mocks such anxious cares,
> His earthen tub no conflagration fears;
> If crack'd or broken, he procures a new,
> Or, coarsely soldering, makes the old one do."
> GIFFORD.

This tub is also mentioned by other authors; but no notice is taken of it by several ancient writers, who have dwelt upon the particulars of the life of Diogenes; and it is therefore doubtful, whether this piece of his history be founded on fact, or whether it ought not rather to be reckoned among the number of those unaccredited stories, which were so frequently invented, related, and believed, in regard to the lives and habits of many of the ancient philosophers.

At an advanced period of life, Diogenes is said to have undertaken a voyage to Ægina; and having met with pirates, he was made prisoner, carried into Crete, and exposed as a slave to public sale. Being asked what he could do, he replied, "I can govern men; therefore sell me to one who wants a master." Xeniades, a wealthy Corinthian, being struck by the singularity of this reply, immediately purchased him; upon which Diogenes told him, that he should be more useful to him as his physician than as his slave. On their arrival at Corinth, Xeniades presented him with his liberty, and entrusted him with the direction of his children's education, and with the management of his domestic concerns; in which situation Diogenes acquitted himself so much to the satisfaction of his master, that the latter used to say, the gods had sent a good genius to his house.

During his residence at Corinth, Diogenes frequently attended the assemblies of the people at the *Craneum*, in the vicinity of the town, and at the Isthmian games; omitting no opportunity of inveighing against the vices and follies of the times, and inculcating the practice of temperance and virtue. It was upon one of these occasions, that the conference between Alexander the Great and Diogenes is said to have taken place. The story is of doubtful authenticity, but it is thus related by Plutarch. After the death of his father, Alexander received the congratulations of all ranks on his being appointed to the command of the Grecian army, in their projected expedition against the Persians. Upon this occasion, Diogenes was absent; and Alexander expressed his surprise at the circumstance. Anxious, however, to gratify his curiosity by the sight of such a celebrated philosopher, he visited the Craneum, where he found Diogenes sitting in his tub in the sunshine. The king approached him amidst the crowd, and said, "I am Alexander the Great;" to which Diogenes replied in a surly tone, "and I am Diogenes the Cynic." After conversing with him for some time, Alexander asked if there was any service he could render him? "Yes," said Diogenes, "not to stand between me and the sun." Surprised at the magnanimity of this reply, the king exclaimed, "If I were not Alexander, I would be Diogenes!" These circumstances are alluded to by Juvenal, in the sequel of the passage already quoted:

> "Even Philip's son, when in the little cell
> Content he saw the mighty master dwell,
> Own'd, with a sigh, that he who nought desired,
> Was happier far than he who worlds required," &c.
>
> GIFFORD.

And the author of Hudibras, with his usual humour, contrasts the unbounded ambition of the Macedonian conqueror, with the philosophical contentment of the Cynic:

> "The whole world was not half so wide
> To Alexander, when he cry'd,
> Because he had but one to subdue;
> As was a paltry, narrow tub to
> Diogenes, who ne'er was said,
> For aught that I could ever read,
> To whine, put finger i'th'eye, and sob,
> Because he'd ne'er another tub."

It has not been satisfactorily ascertained at what period, and in what manner, the death of Diogenes took place. It is most probable, however, that he died at Corinth, of mere decay, in the 90th year of his age, in the 1st year of the 114th Olympiad, or 324 B. C. He was buried by the Athenians in an honourable manner, at the public expence; a column of Parian marble, terminated by the figure of a dog, was placed over his tomb; and his friends and disciples erected many brazen statues to his memory.

At this distant period, it is almost impossible, without the assistance of any authentic written memorial, to ascertain, with any near approximation to truth, what were precisely the substance snd tendency of the doctrines promulgated by Diogenes. The accounts which have been transmitted to us by ancient authors, are confused and contradictory. But there seems little reason to doubt, that he practised the most hardy self-controul, and the most rigid abstinence; that he was earnestly desirous of correcting and improving the public morals; and that he censured, with steadiness and severity, the reigning vices and follies of the age. At the same time, he appears to have carried both the cynical habits and philosophical doctrines of his master Antisthenes, to an extravagant extreme. True wisdom does not require a sacrifice of the common comforts of life; and in the affected humility of Diogenes, there evidently lurked a degree of philosophical pride, not inferior to that of many of the individuals who incurred his censure. "I trample under foot the pride of Plato," said Diogenes, treading upon his robe. "Yes," replied Plato, "with greater pride of your own." From his favourite dogma, "that every act which inferred no moral guilt, might be practised openly under the eye of the public," he is said to have deduced consequences in the highest degree disgusting. But it is difficult to believe, that an individual who has been extolled by some of the most ancient philosophers for his sobriety and virtue, and represented as one endowed with divine wisdom, should have been capable of inculcating such revolting doctrines, or of committing such gross indecencies as have been laid to his charge.

DISAPPOINTMENT, ISLANDS OF, is the name given to a cluster of islands in the South Pacific Ocean, by Commodore Byron, by whom they were discovered in 1765, on account of his being unable to procure any refreshments for his sick crew. The smallest of the two principal islands is about five miles in circumference, and had a most beautiful appearance. It was encircled with a beach of the finest white sand, and was covered with tall trees, which formed the most delightful groves, and extended their shade to a great distance. The natives were of a deep copper colour, and exceedingly stout and well made. They were remarkable for their agility, and astonished Commodore Byron with the extreme rapidity with which they run. They carried large spears about 16 feet long, and would not permit the crew to land on their island. The larger island was also inhabited. The middle of this cluster of islands is in West Long. 145° 4′, and South Lat. 14° 5′. (*j*)

DISAPPOINTMENT ISLAND, is the name of an island in the South Sea, which was discovered by Captain Wilson in 1797. It is one of the cluster called Duff's Groupe, which are about eleven in number, having two large islands in the middle, about six miles in circumference. Several other islands are situated on the north-west side of the groupe, and there is a remarkable rock in the shape of an obelisk at the east end of one of them. The two large islands were covered with wood. The houses were built close to each other; and the natives were stout and well made. The small islands were apparently barren. East Long. 167°, South Lat. 9° 57′. See *Missionary Voyage*, p. 296. (*j*)

DISCORD, in Music, called *Diaphorica* by the ancients, is the peculiar and disagreeable effect on the organs of hearing, excited by two or more sounds, when heard together and united, which are not in certain relation to each other, and are called CONCORDS. See that article. The physical distinction, or cause of the difference between discord and concord, is yet involved in considerable difficulties. We know, however, from experiments, so often repeated and varied as to leave no doubts, that except the eight intervals in the octave (including its extremes, as was done in deriving its name,) which are indeed *concords*, viz. I, 3d, III, 4th, V, 6th, VI, and VIII, and others formed by the addition of an eighth, or of two, three, &c. eighths, (VIII) to each one of these respectively; and excepting also a certain extent of intervals within fixed limits of each one of these concords on each side, which are called *Imperfect Concords*, (and are distinguished by audible BEATS, see that article.) All other intervals whatever, great and small, are *discords*, although having different degrees of unpleasant effect on the ear, as Mr Liston's euharmonic organ is best calculated, of any other method, for exemplifying by experiment.

It has been ascertained, that Beats, or any other noise repeated at uniform periods of time, quicker than 12 or 13 times in one second of time, cease to be heard separately, and unite into a new continuous sound. In the following Table we have calculated the sharp temperaments necessary to be applied to each of the concords in the octave above the tenor cliff C, in order to produce 12 beats in a second in each case respectively, viz.

VIII	C	$\frac{1}{2}$	480	21.8806
VI	A	$\frac{3}{5}$	400	8.8172
6	A♭	$\frac{5}{8}$	384	5.5210
V	G	$\frac{2}{3}$	360	14.6470
4	F	$\frac{3}{4}$	320	11.0079
III	E	$\frac{4}{5}$	300	8.8172
3	E♭	$\frac{5}{6}$	288	7.3537
I	C	$\frac{1}{1}$	240	43.2340

In the 1st column the intervals are expressed, in the 2d the notes, in the 3d the ratios, in the 4th the complete vibrations in 1″ made by each note, and in the 5th the sharp temperaments, which will produce 12 beats in 1″, expressed in schismas, whereof 614.212639 make the octave.

The grave temperaments of each of these concords will be a little less, respectively; but if we suppose them equal, and we double all the temperaments but those of I and VIII, and add these to the product, we have about 177 Σ for the extent within which imperfect or beating concords can be produced in this octave; and the remainder, or 437 Σ nearly, will produce discords only. Whence it appears, that if any two sounds are produced at random, within the limits of his octave above the tenor cliff, the chances are nearly as $3\frac{1}{2}$ to 1 that they will produce a discord, instead of a tempered or beating concord, or a perfect concord, for which last effect the chances are very few.

By the above Table it will be seen, how very unequal the limits are, within which the concords produce *beats* respectively. In the next superior octave, the halves of these numbers, and in the next above the halves of these again; in the next octave below tenor-cliff C, the double of these numbers, and 4 times in the next descending octave, will produce approximate sharp temperaments of the concords respectively, for producing 12 beats per second, such as Dr Smith deduces from the *ultimate ratios*, ("Harmonics," prop. xi. cor. 3.) but which are not exact, as will be seen by multiplying each of our numbers in col. 5. by the denominator of its fraction in col. 3, which will not invariably produce a product of 43.2340, as would be the case, if the ultimate ratios were the very same as the true ratios, that are used in the 2d and 4th method of calculating, in our article BEATS. (*g*)

DISCOUNT, in trade, is expressive of an abatement allowed in consequence of anticipating a fixed period for payment. When a bill has two months to run, and a banker gives money for it on receiving the two months interest, the interest so received is called discount. When a warehouseman sells goods at ten months credit, but on receiving ready money, consents to abate $7\frac{1}{2}$ per cent. the sum abated is called the discount. The extent of discount granted in this manner by persons in trade, is larger than might be inferred from the magnitude of the commercial capital in this country. Ten per cent. for twelve, or at least for fourteen months, is quite common in London. The greatness of this discount is owing to the risk that would be incurred by the seller in giving credit, as well as by his extending his trade beyond his capital. In this, as in other respects, the political economist has ample reason to lament the effects of expensive war. The vast sums levied by government in loans and taxes operate to keep the money market bare, and to prevent the application of the funds of capitalists to commercial purposes. At different periods in the course of last century, the interest of money was 4 per cent. but during the last 20 years, it has been 5 per cent. and by no means easily procured at that rate. Were we to investigate the disclosures made in courts of justice in regard to annuity transactions, we should be surprised to find that 10 per cent. had, not unfrequently, been paid on security, which, to most persons, would appear to entitle the holders to pecuniary accommodation at a much lower rate. In Holland, in the days of her commercial prosperity, the rate of interest was remarkably low. Three per cent. and frequently two and a half, might be put down as the current premium on good security for the century preceding the unfortunate war of the present age. In France, on the other hand, interest has been all along much higher than with us. Though the rate of discount on bills does not exceed 6 per cent. we believe that for a permanent loan, it is not uncommon, in that country, to obtain 8, 10, or 12 per cent. with security which is generally accounted unexceptionable.

In several branches of trade in this country, it is common for the seller to tempt the buyer with the offer of a large discount; 15, 20, and even 25 per cent. being frequently allowed in this manner. Such a practice ought not to be encouraged, the allowance being a mere delusion. It needs no proof to shew, that whatever is deducted in this way must be previously added to the charge of the goods, and that the same result would be attained by stating, in a single line, the lowest ready money price. This custom has farther the bad practical effect of awakening the suspicion of foreign merchants, who, hearing that in certain lines large discounts are allowed, may be inclined to consider the practice in the light of a collusion between their correspondent and the manufacturer of whom he makes his purchases. As trade improves in the mode of its management, the habit of discount, at least of large discounts, may be expected to give way. The buyer coming with money in his hand, will go the shortest way to work, and the seller will find it his best policy to say at once the least price which he can afford to take.

Bankers and other persons discounting bills, take payment of the interest at once, without waiting for the lapse of the specified term of days or months. Whether this be strictly in the spirit of the law, we do not pretend to determine. Its practical result is to afford the banker, in the case of discounts frequently repeated, an interest of $5\frac{1}{4}$ or $5\frac{1}{2}$ per cent. for his money during the year. This, however, is no grievance, as the applicants are aware of it, and as, in the season of war, it is generally a favour to discount bills on those terms. In peace, there is seldom room for complaint, as interest frequently falls below the legal limit, 4 per cent. being the ordinary allowance in times when government has not occasion to make heavy demands on the money market. (χ)

DISDIAPASON, in Music, (XV) or Bis-diapason, is a concordant interval or concord, whose ratio is $\frac{1}{4}$, $=1224\Sigma+24f+106m$, the double octave, 2VIII, or Fifteenth *Major*, which see.

DISDIAPASON, *Diapente* (XIX), this concord is $2VIII+V$, and has a ratio $\frac{1}{6}$, $=1582\Sigma+31f+137m$. See Nineteenth *Major*.

DISDIAPASON, *Diatessaron* (18th), is $2VIII+4th$, and this concord has a ratio $\frac{3}{16}$, $=1478\Sigma+29f+128m$. See Eighteenth *Minor*.

DISDIAPASON, *Ditone* (XVII), this concord is $2VIII+III$, and has a ratio $\frac{1}{5}$, $=1421\Sigma+28f+123m$, See Seventeenth *Major*.

DISDIAPASON, *Semiditone* (17th), is $2VIII+3d$, and this concord has a ratio $\frac{5}{24}$, $=1385\Sigma+27f+120m$. See Seventeenth *Minor*.

DISKO Bay. See Greenland.

DISMAL Swamp, Great, is the name of an immense bay on the confines of Virginia and Carolina, extending about 30 miles from North to South, and having a medium breadth of about 10 miles. Reeds, about 12 feet high, interspersed with Bamboo briars, cover the north east margin of the swamp, while the southern margin exhibits a large track of green waving reeds, which has received the name of the Green Sea. An evergreen shrub, called the gall bush, with a berry that gives a black dye, is found here in abundance. Near the middle of the swamp, both cypress and cedar trees grow in abundance; but they are easily blown down by a moderate wind. No living animal is found in the neighbourhood, the noxious vapours being prejudicial to animal life, and engendering agues and other disorders. Five navigable rivers have their origin in this swamp, namely the south branch of Elizabeth river, and the south branch of Nansemond river, both of which flow into Virginia, and the North River, North West River, and Perquimons, which run into North Carolina. The sources of these rivers are concealed in the swamp, and must therefore be supplied from some subterraneous springs, or by the water that runs into the swamp from the high lands. The last of these suppositions is the most probable, as the swamp is a mere quagmire, which shakes under the feet of those who walk upon it, every mark of the foot being instantly filled with water. On the western margin of the Dismal is a pine swamp above a mile broad, the greatest part of it being covered with water about two feet deep. The bottom being firm, the pines grow to a very great height, and are not easily overthrown by the wind. Notwithstanding these disadvantages, some parts of the Dismal exhibit scenery by no means unpleasing. Fragments of trees are found buried and preserved under the vegetable earth, at different degrees of depth, as in the plains which rise in the form of a terrace near the bed of the river Connecticut. When dug out of the ground, they are soft, but they grow hard by exposure to the air. The Duke de Rochefoucault remarks, that the Dismal Swamp has less solidity than any which he has seen; but that the earth which is dug out of it hardens in the air, and forms an excellent dike.

In the middle of Dismal Swamp is a lake about seven miles long, called Drummond's Pond, which discharges its waters to the south, into Pasquotank river, which runs into Albemarle Sound, and on the north into Elizabeth and Nansemond river, which flow into James' river.

In 1777, a canal was forming through Dismal Swamp. It was to pass about a mile East of Drummond's Pond, and was to unite the south branch of Elizabeth river, or rather of Deep-Creek, which falls into it, with Albemarle Sound, by means of the river Pasquotank. The canal company was incorporated by the legislature of North Carolina and Virginia. The length of line is 28 miles, and the soil through which it lay was very easily wrought. In 1796, five miles had been dug on the Virginia side, and as many on the side of North Carolina, so that only 18 remained to be cut, which they expected to accomplish in three years.

The principal object of this canal is to shorten and facilitate the communication between North Carolina and Norfolk. It will thus open an inland navigation from the head of Chesapeak Bay, including all the rivers in Virginia, to George town in South Carolina; and when the canal from Elk River to Christiana Creek is opened, the communication will extend to Philadelphia, and to the ports connected with Delaware river. The Swamp principally belongs to two companies; the Virginia Company, which possesses 100,000 acres; and the North Carolina Company, which possesses 40,000. See Morse's *American Gazetteer*, and Rochefoucault de Liancourt's *Travels through the United States of North America, in* 1795, 1796, and 1797, vol. ii. (*w*)

DISNIA. See Dissima.

DISPASIS, a genus of plants of the class Gynandria, and order Diandria. See Botany, p. 313.

DISPERSION of Light. See Achromatic Te-

LESCOPE; but particularly OPTICS, where our readers will find the most copious table of *Dispersive powers* that has yet been published.

DISS, a market town of England, in the hundred of Diss, of the parish of Norfolk. It is said to derive its name from a large muddy pool of water, lying on the south side of the town, and abounding with eels. Diss is situated on the northern bank of the river Waveney, which here separates the counties of Norfolk and Suffolk. It consists of several streets, the principal of which are paved, and the houses have a comfortable and respectable appearance. The church consists of a chancel, nave, and two aisles, with a square tower at the west end, and is remarkable for the cleristory tier of windows. They are arranged in pairs, five of which are on each side of the nave, and there is a plain pilaster between each pair. The arch which forms the head of the windows is a waving line. There is a semicircular arch above the door of the south porch, and over it is a window formed of seven arched lights. The other establishments are a neat Presbyterian and Quaker meeting, and a charity school, kept in a building which was formerly the guild-hall.

In the year 1773, when a vault was sinking in the church, the workmen discovered a stone coffin containing a skeleton in high preservation, with a pewter chalice near the head; two large empty earthen urns were found near the coffin. The principal manufactures of this town are hempen cloths, hose, and stays.

The following is an abstract of the population return for the parish of Diss in 1811.

Number of inhabited houses,	348
Families that occupy them,	520
Ditto employed in agriculture,	69
Ditto in trades and manufacture,	78
Males,	1181
Females,	1409
Total population in 1811,	2590

See Blomefield's *History of Norfolk*; and Evans' and Britton's *Beauties of England and Wales*, vol. xi. p. 228, 229. (*w*)

DISSIMA, DISNIA, DISMA, or more properly DEZIMA, is the name of an island or peninsula of Japan, situated near the town of Nangasacki. This island is about 600 feet long, and 120 broad, and is separated from the town and mainland, at low water, by a ditch, over which there is a bridge to form the communication at high water. This island is planked in on all sides, and has two gates, one towards the town near the bridge, and the other towards the water side. The first is always guarded in the day-time, and locked at night, and the latter is only open when the Dutch ships are loading or unloading.

This island is let to the Dutch Company by the inhabitants, who build and keep in repair all the dwelling houses. The emperor's edicts for the regulation of the Dutch trade, are hung up on several tables, upon a large stone pillar, at the entrance of the bridge; and such is the jealousy of the Japanese government, that they have three watch houses in the island, and a guard-house where every person is searched. The Dutch are not even permitted to converse with the guards or with the natives, excepting those who are appointed factors and brokers by the governor of Nangasaki. They were not even allowed to have lighted candles in their houses, or on ship-board, and if any noise or disturbance was heard, the ottonas or reporting officers immediately gave notice of it by blowing a horn, and a party was instantly dispatched by the governor, to inquire into the cause of it.

The houses and store-houses of the Dutch Company are built lengthwise upon the island, in the form of a small town. They have also an hospital, and separate houses for their servants, who inhabit the upper story, while the lower one is filled with stores and lumber. Two streets crossed by a third, run between these store-houses. The store-houses are all fire-proof, but the dwelling houses are made of wood and clay, and covered with tiles, and have paper windows, and straw mats for the floor. The interpreters have a large house on the island, called their college, and there is another house for the ottonas. According to the observations of Krusenstern, the flag-staff of Dezima is in north latitude 32° 44′ 18″. The east longitude of the centre of the town of Nangasacki, according to the same observations, is 30° 7′ 53″. See Krusenstern's *Voyage round the World*, vol. i.; and Milburn's *Oriental Commerce*. DISTILLATION,

A PROCESS in chemistry, by which one body is separated from another, by taking advantage of the relative temperatures at which they assume the elastic form, and afterwards condensing the vapour in a separate vessel.

When the vapour condenses into the solid form, such as sulphur, corrosive sublimate, calomel, &c. the process is termed sublimation. In this case, the substance to be distilled may be placed in the bottom of the vessel where the heat is applied. The vapour rising to the upper part, adheres to it. It is more common to have an upper vessel inverted directly over the lower one, for the reception of the vapour, which, when it is condensed upon its interior surface, can be removed in the form of a cake. The sub-ammoniac of commerce is sublimated in this form, and also corrosive sublimate and arsenic.

When the condensed vapour is obtained in the liquid form, the shape and situation of the vessels are very different. The vapour should be kept completely in its elastic form, to a certain height. The neck of the vessel should then turn by a sharp curve, on an elbow, so that the substance, after condensation into the liquid form, may, by its gravity, descend as quick as possible. The height of the elbow above the point where the heat is applied, should be only sufficient to guard against the mass below getting over the neck, by boiling or any other cause of agitation. When the neck of the lower vessel is liable to be long, it should be defended in some way, either by being polished or clothed, to prevent the escape of heat, in order to allow the vapour to be carried over into the descending part, before it condenses. The vessel from which the vapour rises, when of large size, and used for distilling simple liquids, is called a *still*. Those used for experiments in a small way, and also for distilling acids, ammonia, ether, &c. are called *retorts*; the vessel that receives the distilled matter being called a *receiver*. See *Chemical Apparatus*, under CHEMISTRY.

The retort is the most simple of the distilling apparatus, but it can only be employed when the vapour is easily condensible, or when little heat is applied. When expedition is an object, recourse is had to a more compound apparatus, by which the condensation is facilitated. It is to this that the name *still* is more properly applied.

The most simple of this variety is the alembic. It consists of a lower vessel, terminating in a narrow neck, which, with the substance that is to be distilled, is applied to the fire. At a certain height, depending on the nature of the substance, is placed upon the neck, a spacious vessel, which is exposed to the air, or kept cold by a supply of cold water, in order to condense the vapour as quick as possible. If exposed to the air, it should be painted of japanned black. Round the bottom of the interior is a projecting channel to receive the liquid arising from the condensation of the vapour, which runs down the sides of the open vessel, in preference to falling back into the still. From this channel, the liquid descends by a pipe, placed at a certain angle into a receiver. This apparatus is sometimes made of glass, for small experiments, but more frequently of metal. It is at present not often used, the condensation by the worm tub being much more effective.

When the worm tub is employed, the still requires to have such a shape, that the greatest possible surface may be exposed to the fire. For this purpose, it is made in the form of a frustum of a cone, the base being as large as convenient, and the altitude very little. The neck should be of such width, as to convey the vapour as fast as formed. The height of the neck is regulated by the nature of the substance. If it is mucilaginous, such as the wash from which spirit is distilled, the neck should be longer, to prevent its boiling over. The exterior surface of the descending part of the neck, in this case, should be polished, to prevent the escape of heat. The descending part, at the same time, should be painted black. The end of the latter is inserted into the neck of the worm.

The worm tub consists of a wooden vessel, about six or eight times the capacity of the still. The length to the diameter is about 10 to 7. The worm consists of a spiral tube, which enters on one side of the tub, at the top: it then passes spirally, in about six or eight convolutions, to the bottom, where it comes out of the side, in order to discharge the liquid arising from the vapour condensed within it, by the agency of the cold water, with which the tub is filled. The water is constantly changing, by the warm water running away from the top, whilst a supply of fresh cold water comes in at the bottom. The section of the tube being a circle, its capacity should not be less than one-fifth of that of the still: the diameter of the ends of the tube being about three to one. The object is not merely to effect a condensation, but to cool the liquid, so that it may be less liable to evaporation after coming over. The proportions of the means of condensation to that of evaporation, will not always depend upon the relative sizes of the vessels, but will be governed by the quantity of vapour supplied in a given time, and the supply of cold water. In order to enter into the subject theoretically, by which we shall be enabled to give a more enlightened view of this branch of art, we shall divide it into two heads, namely, *Evaporation* and *Condensation*. The first will comprise the quantity of heat taken by different liquids to become vapour, and the means of furnishing the heat at the expence of fuel, with the best means of applying and regulating the latter. The second head will embrace the transference of the caloric from the vapour to some other medium, such as cold water, and the means of furnishing an adequate supply. To the above it may be necessary to add the different means of rendering substances less volatile which are not intended to rise, and of giving greater volatility to those which are wished to be procured.

In the application of fire to a vessel containing a substance to be evaporated, the fire should be so placed upon a grate, that a due supply of air may be admitted to produce a vigorous combustion. No air should be supplied but through the grate; and the quantity of heat will be the greatest, when no more air enters than is sufficient for the combustion, an excess serving only to cool what the fire has heated. The escape of the smoke and hot vapour should be at a point not higher than the level of the grate. This is to prevent the heated matter from escaping before it has parted with its heat to the vessel, by which its specific gravity is increased, and it descends in consequence. When the bottom of the vessel to be heated is circular, which is the case with the common spirit still, the exterior surface being also concave, the fire should be placed in the middle of the circle. The flame and heated vapour first rises up against the middle of the concave bottom; it then should take a direction towards the periphery of the circle; but, at the same time, it should have descended as low as the level of the grate. It should now enter the flue through a narrrow neck, which extends through the whole periphery of the circle, and which opens into the flue all round. This narrow aperture, which would be liable to be filled with soot and the light ashes, should be provided with a rake, which should work in the circumference of the circle: This being pushed, by a handle, to the right and left, on the outside, from time to time, keeps the circular neck clear. This long narrow aperture prevents the rapid escape of the heated vapour, before the heat is expended upon the vessel, and will be found much superior to the plan of labyrinthal flues in economising fuel. From what has been observed, it will be almost needless to suggest, that the greater the diameter of the vessel to be heated, the more completely will the vapour give out its heat, having, in this case, to make a longer rout to get to the flue. Hence it will appear, from this and other reasons, that the form of a still should be such, that its diameter will admit of the greatest possible quantity of heat being given out upon its bottom. Its depth, at the same time, should be the least possible, in order that the surface of the fluid may be as near as possible to the source of heat. The economy of the fuel will be still more increased, by having a double door to the fire-place. The size of the fire-place should vary with the quantity of liquid required to be distilled in a given time. In the Scotch distilleries, where the duty is paid for the time the still is employed, it is the interest of the distiller to apply the heat in such a way, as to get the greatest produce in a given time. It should be recollected, however, that this expedition is attended with bad consequences, so far as regards the purity of the spirit. When the ebullition is violent, which must be the case in the expeditious way, there is greater risk of the matter getting over in the liquid state to a certain degree, by which the distilled product would be liable to be contaminated. We are informed, that in some of the Scotch stills, as much as 160 gallons is drawn from a 500 gallons still in 20 minutes. Supposing one-third of this product to be spirit and the rest water, the spirit would require an expenditure of 26 lb. of the best Newcastle coal, and the water 107 lb.; making 133 lb. or nearly $1\frac{1}{3}$ bushels of coal. This is more by half a bushel than is consumed by a steam engine of 40 horse power. The means of condensation in a process so rapid must have been also very great. The vapour of the 53 gallons of spirit, during its condensation, would raise the temperature of 340 gallons of water at 50° to 120°, while the vapour of the 107 gallons of water would raise 1440 gallons of cold water through the same range of temperature. The total supply of cold water in 20 minutes would, therefore, be 1547 gallons, or 77.3 gallons in one minute.

When the distillation is very rapid, as in the instance above alluded to, the wash, or fermented wort, from which the spirit is drawn, abounds with so large a quantity of mucilage, and other vegetable matter, that it is very liable to deposition. This matter is apt to burn on the bottom of the still, producing an empyreuma, which gives a disagreeable flavour to the spirit. This evil, however, is in a great degree obviated by a piece of machinery, which works in the still by a motion communicated from the outside. It consists of a rake, which is constantly turning in contact with the bottom of the still. In the first distillation from the wash, in which about one-third of the whole is drawn off, this apparatus is absolutely necessary. This product is called *singleings*. This last undergoes a second distillation, from which about one-third of the whole is drawn. In this stage, it will be evident, that the machinery for raking the bottom will be unnecessary.

In the second distillation it will be proper to remark, that, in consequence of the distilled product being almost wholly spirit, the means both of evaporation and condensation will require to be less. The quantity of caloric required to raise water into vapour, is about 1 lb. of coal for every gallon of water. The latter will then require about 13 gallons of water at 50° to condense it, and reduce it to the temperature of 120°. The same quantity of heat will raise a little more than double the quantity of pure spirit into vapour. The same fuel and cold water, therefore, which would be expended on one gallon of water in its distillation, would distil more than two gallons of spirit. Count Rumford has lately ascertained, that the quantities of heat required to raise water and alcohol into vapour, are something more than 2 to 1; and he is of opinion, that ether requires about one-half the quantity of heat with that of alcohol. Hence we should conclude, that the means of evaporation and condensation for water will be four times that required for *ether*.

Besides the alcohol, which comes over with greater facility than the water, there are other volatile matters which are furnished by the vegetable substance from which the fermented liquor is procured. These are essential oils, which are different in the different fermented liquors. When they are from wine, or from the wash made from sugar, their aroma is rather of an agreeable flavour, and the rectifier becomes less anxious about their separation. Those essential oils which are afforded by the wash made from malt, or other grain, are very disagreeable to the smell; and, in this case, the purification of the spirit has long been a desirable object to the rectifier.

The rectifier buys his spirit from the distiller, in the state of what is called raw spirit. This generally abounds with all the impurities which are volatile, little or no pains being taken to purify the spirit in the first process. Every rectifier has his secret for purifying his spirit. It very often happens, however, that, instead of removing the offensive aroma, he substitutes one which overpowers and disguises the original. This is mostly the case in the different kinds of gin, and other compound cordials. In some instances, when the spirit is very weak, and the essential oils are abundant, the water exerts a greater attraction for the alcohol than that of the alcohol for the oil; by which means the oil becomes free in the liquid, giving it a turbid and milky appearance. In this case, the separation of the oil becomes an object. It is common to add alkalies for the purpose, forming saponaceous compounds with the oil, by which it acquires a greater degree of purity, and is less liable to rise in the rectification, which consists in distilling with a moderate heat. Acids have the property of converting essential oils into resinous substances, by which they become less volatile, and are, in consequence, easier to separate from the alcohol by distillation with a low heat. The rectifier employs a distilling apparatus similar to the distiller in every respect, but he proceeds with more care in the application of his heat.

Distillation of water.

In the distillation of water, so constantly required in medicine and in the laboratory of the chemist, much more precaution is found necessary than was formerly thought to be the case. The impropriety of distilling river waters, or others liable to contain animal and vegetable matter, it will be needless to point out, as it is well known that such distilled water is liable to putrefaction. The water to be distilled should be the most complete spring water, taken from some place where it has not run over any vegetable soil. If it contain muriate of lime, or any other very deliquescent salt, these salts are found to rise with the water, and never fail to exist in the distilled water. When the water to be distilled contains muriate of lime, the addition of a little soda decomposes the salt, producing muriate of soda and lime, neither of which will rise in distillation. It is owing to the presence of the muriate of lime in sea water, that has rendered it so difficult to purify it by distillation.

The distillation of what is called crude ammonia, or hartshorn, is carried on upon a large scale in several parts of the kingdom. The materials to be distilled are in general bones and hoofs of animals. On some occasions urine is used for the same purpose.

Distillation of bones.

In the distillation of bones, an iron still is generally used, with a pipe leading from it, connected with a worm tub, similar to that already described. The vessel being filled with bones roughly broken, a strong heat is applied. Water and animal tar first come over, accompanied by a very fetid inflammable gas: Carbonic acid gas also comes over, but the latter is mostly taken up by the ammonia, which is also formed at the same time. These come over into the receiver in the state of carbonate of ammonia. When the different substances have been condensed in the worm, they should pass into a receiver, which has no communication with the open air. This would not only render it almost impossible to exist in the same place, but would constitute a nuisance in the vicinity of any town.

The receiver should have no opening outwards, but through a pipe inserted into the upper part of it, and connected with the fire of the still. The inflammable gas and the smell are conveyed to the fire, where the former takes fire and burns. It may be proper here to hint one precaution, to avoid an accident: When the evolution of the inflammable gas becomes slow, or ceases entirely, the common air comes with the flame along the pipe into the close receiver, which is filled with the same inflammable gas. Under these circumstances an explosion will take place, which will not only burst the receiver, but do other injury. This evil will be avoided, by placing a valve in the pipe opening outwards, and another upon the receiver opening inwards: By this means the flaming gas will be stopped in its passage to the receiver, while the valve into the receiver will open to admit the common air, to fill up the vacuum. By means of the above apparatus, if it be well constructed, and proper luting employed, the distillation of hartshorn may be carried on almost without smell.

The first product consists of water, animal tar, and carbonate of ammonia. A great part of the tar may be separated mechanically; the rest is subjected to a second distillation with a gentle heat. The liquid which comes over consists of a solution of carbonate of ammonia, with a fetid animal oil, which gives it a peculiar odour. This liquid has been sold in the shops under the name of spirit of hartshorn. The animal matter contained in this substance, was at one time thought to possess certain medical virtues. This idea becoming obsolete, has led to the substitution of what is termed the aqua-ammonia. This is formed by distilling the muriate or sulphate of ammonia and quicklime. The lime takes the acid from the salt, setting the ammonia free, which comes over in the state of gas, and is absorbed by water. This liquid is called aqua-ammonia.

In the manufacture of printed calico, a large quantity of acetic acid is employed, for the preparation of certain mordants. The acetic acid used for this purpose, is procured from wood by distillation.

Distillation of wood.

The still is made of cast or wrought iron, and very strong, so as to bear a red heat. The wood is piled up in the still in the state it is used to make charcoal. The heat required is similar to that required for distilling bones. Water and vegetable tar, with acetic acid, come over, accompanied by the carbureted hydrogen gas. The former of these products are condensed in the worm, and run into a receiver. The gas escapes at an aperture for the purpose, and is sometimes burnt, to illuminate the place. It would be advisable to let the gas pass under a gasometer, in order to preserve it for burning, and also to prevent the disagreeable smell which accompanies the process. The gas furnished in this process, is very similar to that furnished by the distillation of coal. Indeed, there is some analogy in the distillation of animal, vegetable, and mineral coal. In the first, there is ammonia, and a substance having all the properties of tar, but much more fetid, owing to the presence of sulphur, and probably phosphorus; there is also furnished an inflammable gas, which is doubtless carbureted hydrogen mixed with other gases, holding a portion of sulphur and phosphorus.

In the distillation of wood there is no ammonia, but, instead of it, acetic acid. The gas is similar, with the exception of the difference caused by the presence of the sulphur and phosphorus. In the distillation of coal, no acetic acid appears to be formed, but a small portion of carbonate of ammonia: this would show it to be more allied to the animal than the vegetable substance. The gas furnished by coal, is principally the carbureted hydrogen. It contains also a little sulphureted hydrogen, to absorb which, a portion of limewater is used to pass the gas through. The distillation of coal, for the purposes of furnishing gas for the gas-lights, is at present carried on with great advantage, the gas being a valuable substitute for oil and tallow. The coak left in the still, is superior to that made in the common way; and the tar might be used for many purposes, either in the liquid form, or in the state of pitch, which it assumes by evaporation. The residuum from the wood forms excellent charcoal. That from the bones of animals is generally ground down into powder, and sold for ivory black. The coaly residuum from other animal matter, such as hoofs and blood, is used for making Prussian blue. In the distillation of any of these substances, it will be profitable to know, that if the retorts or still, which is of cast iron, be allowed to cool every day, that it will be soon destroyed by the oxygen of the air; but if it be constantly kept at work, by discharging and re-charging it without cooling, the vessels will wear for several years. This will be found a valuable fact to those who have not yet adopted the plan.

Distillation of mercury.

The only means of obtaining mercury in a state of purity, particularly when it is alloyed with other metals, is by distillation. Nothing can answer better for this purpose than an iron retort, having a long tube of the same metal terminating over a vessel of water. The mercury rises at 600° of Fahrenheit, so that a common fire is quite sufficient for the process.

Distillation of phosphorus.

The distillation of phosphorus is attended with more difficulty than almost any other substance. The heat required is considerably above that of a red heat. The retort is required to be of earthen ware. If the substance of the retort be very open, the sublimed phosphorus escapes through it in the state of vapour. If the substance of it be very close, it is in danger of breaking in the bringing up. It is the best, therefore, to make the body a little open, and cover the surface with flint and borax to form a glazing, which prevents the vapour of the phosphorus from escaping. The retort containing the charcoal and the phosphate of lead, should be placed upon a stand in the middle of a small air furnace, the neck passing through an opening in the side. The end of the neck is firmly luted into a glass receiver filled with azotic gas, from whence a small tube passes into a pneumatic apparatus. The fire is raised very gradually. Soon after the retort becomes red hot, the phosphoric acid begins to be decomposed. A portion of water is also decomposed at the same time. The hydrogen unites to a portion of the phosphorus, forming phosphoreted hydrogen gas, which passes through the receiver into the pneumatic trough, along with a large quantity of carbonic acid gas. Ultimately the phosphorus comes over, condenses in the neck of the retort, and runs into the receiver, which contains a little water for its reception. See *Phosphorus* under CHEMISTRY.

Lutes used in distillation.

In most of the processes of distillation, particularly in the small way, substances called lutes are of great importance. When the heat is not much more than boiling water, common flower paste, spread on linen cloth, forms a good lute for uniting the joinings. Linseed meal made into paste with water, is also used in the same way. A paste, made with clay and oil, or common glazier's putty, is very suitable when the heat is not great, as in that case it becomes very soft. The white of egg, or the serum of blood, or skimmed milk made into a paste with lime, forms an excellent lute for all temperatures under 300° of Fahrenheit. In the distillation of oxymuriatic acid gas, bees-wax is sometimes used, but plaster of Paris is much better. This answers very well in the distilling of nitric acid, as it has no action upon it. When the joining is between two glass tubes nearly of the same size, a piece of wet bladder being firmly wrapped round the joining, adheres as it dries, and forms a very secure and permanent lute.

When the juncture is exposed to a red heat, or higher, sand and clay, with a large proportion of the former, answers very well. This will be much improved by a little horse dung worked up with it. If the heat be such as to produce vitrification, a portion of borax or potash may be mixed with the above. See *Description of Chemical Apparatus* under CHEMISTRY.

Different modes of applying the heat.

In different processes of distillation, there are various modes of applying the heat. When violent and sudden heat would be liable to injure the material of distillation, or when accidents might arise from such effect, the sand bath is generally used. If the sand be not a sufficient conductor to bring sufficient heat to the body, it should be mixed with a greater or less proportion of copper or brass filings. When the heat is not required greater than that of boiling water, the retort or still is placed in boiling water, which constitutes what is called a water bath. It will be found more convenient to bring steam from a boiler at a distance, and allow it to condense upon the distilling vessel. If the steam be brought into the interior of a vessel, having on the outside a dished cavity for sand, the steam may be made of greater density than under the common pressure, and by that means give a greater heat than 212°. Indeed, if the steam vessel be provided with a safety valve, any degree of heat short of endangering the vessels may be obtained with great exactness and uniformity.

When the vessels are of metal, if the abrupt heat does not affect the substance, the naked fire may be used. If the vessels be of glass, or earthen ware, then the naked fire would be very liable to crack them, on account of their inferior conducting power, connected with their frangibility. In this case the sand bath, on the application of steam, is very proper. In experiments of the laboratory, the Argand lamp is found the most convenient method of furnishing heat, as well for distillation as for evaporation and other purposes.

The lamp is fixed, capable of sliding upon a standard. Above, and directly over the lamp, is a sliding ring, to support the retort at any distance from the lamp. The lamp being of the Argand kind, admits of any degree of adjustment, by which the heat may be modified, independent of the distance of the retort from the lamp. The greatest advantage of this mode of giving heat, is in its instant application without loss of time, and being able to withdraw the heat at pleasure.

If, instead of the ring for supporting the retort, a vessel open at top and bottom, in the shape of a frustum of a cone, be used, the heat will not only be much economised, but be returned within the sides of the hollow stand. The retort is placed so as to fit the top aperture. The depth of the vessel is half the width at the base. Instead of a glass, as in the Argand lamp, an iron tube is used. (C. S.)

DISTORTION, in *Optics*. See ANAMORPHOSIS.

DISTRESS, (*districtio*,) in English law, in a more common and limited sense, signifies, a taking of moveable goods, profits of lands, or other personal chattel, by way of pledge, for an injury committed by the owner or possessor. It requires no writ, or judicial process, to constitute its legality, and is accordingly ranged by the writers on the law of England, among those methods of redress which are competent by the mere act of the party. The *thing taken* is also, in common language, frequently called a distress.

The injuries for which a distress may be taken are various; but they have been conveniently distributed into five sorts or classes. 1st, The most ordinary sort is that of non-payment of rent, for which a distress is competent to a landlord against his tenant; and, in this respect, it is analogous to the *landlord's hypothec* of the Scotch law. Nor, whatever may have formerly been the rule, is this remedy confined to any particular sort of rent, but is now extended by statute to every description of rent, whether *rent service, rent charge*, or *rent seck*; so that all arrears are alike remediable by the operation of a distress. 2d, For neglecting to do suit to the lord of the manor's court, or other personal service certain, a distress is competent to the lord of common right. 3d, Amercements awarded in a court-leet, but not in a court-baron, (unless by a special prescription,) may be made good by a distress of common right. 4th, Where a man's cattle, or other beasts, stray into his neighbour's grounds, *damage faisant*,---in other words, injuring his pasture, or occasioning other damage, he may *distrain*, or take them in pledge, till satisfaction of the damage. This species of remedy is also competent by the Scotch law, called a *poinding of cattle*. Lastly, there are several duties and penalties created by certain statutes, for the recovery of which, distress, and subsequent sale, is given.

With regard to the sort of property liable to a distress, the general rule is, that all personal chattels are subjected. There are, however, certain exceptions, such as dogs, rabbits, and all other animals *feræ naturæ*, these not being presumable property of the wrong-doer; also the instrument or tool with which a person is actually working, or the horse he is riding, these being privileged for the time, by reason of the personal use or occupation; also whatever is merely in the wrong-doer's possession in the way of trade, as cloth in the dyer's work-house, a horse in a public stable, &c.; also the tools and utensils of a man's trade, beasts of the plough, *averia carucæ*, and sheep, which kinds of property are all privileged by the ancient common law; also whatever is liable to spoil by keeping, as milk, fruit, &c.; and lastly, whatever is fixed to the freehold, as doors, chimney-pieces, &c. although by statute ii. Geo. II. c. 19, growing corn is now subjected.

At common law, whatever was taken by distress, could not be disposed of for satisfaction of the injury, but only retained by way of pledge until replevied, (*replegiare*,) or got back by the wrong-doer, under security of satisfying the distrainer's claim; and thus still stands the law with regard to distresses of beasts taken *damage faisant*. But now by various acts of parliament, all other distresses, if not replevied by the owner within a longer or shorter period as the case may be, may be sold by the distrainer in satisfaction of his claim, and the overplus, if any, restored to the party. (J. B.)

DISTRINGAS, in English law, is a writ, by which the sheriff, or other officer, is commanded to distrain a party in satisfaction of a debt due to the king, or to compel him to some act of obedience to the law.

First, By this process, a party may be compelled to make appearance in the courts of common law, to answer to the plaintiff's suit. If one distress has no effect, the sheriff may proceed from time to time, and continually; and hence it is called a *distress infinite*. By the common law, the goods so taken were forfeited to the king, if the party remained obstinate; but now by statute 10 Geo. III. c. 50, they may be sold, if the court shall so direct, to defray the plaintiff's costs. It is by this process also, that the courts of equity enforce obedience to their summonses or directions against a body corporate, the process of these courts being different in the case of an individual. *Second,* It is likewise used as a compulsive process against jurors, to compel their appearance against the day appointed. And, *third,* Where a defendant has been adjudged to render or do something in special, he may, under this writ, be compelled by repeated distresses of his chattels.

A *distringas* differs from a common *distress* in this, that the one is a judicial process, sanctioned by an express writ; while the other is entirely the act of the injured party. The sole object of the former also, is the redress of a private wrong; while the latter is rather in the way of punishment, for contempt of the authority of the court. (J. B.)

DITASSA, a genus of plants of the class Pentandria, and order Digynia. See Brown, *Wernerian Transactions,* vol. i. and BOTANY, p. 181.

DITMARSH. See DENMARK, and HOLSTEIN.

DITONE, in Music, (III) or Ditonum, $T+t$, is a concordant interval whose ratio is $\frac{4}{5}$, $=197\Sigma+4f+17m$, or the THIRD *Major,* which see.

DITONE of *Aristoxenus,* in his genus Enharmonic, was $\frac{24}{30}$th of the minor fourth, or $\frac{4}{5}\times 4th$, $=203.20471\Sigma+4f+17m$, or $203\frac{1}{5}\Sigma+4f+17\frac{3}{4}m$, and its log. $=.9000490,1071$.

DITONE of *Eratosthenes,* according to Dr Wallis, had a ratio $\frac{15}{19}$, $=208.72902\Sigma+4f+19m$, and its log. $=8973376,5811$. This is the greater of the equal-beating bi-equal thirds of Earl Stanhope. See the *Phil. Mag.* vol. xxvii. p. 203.

DITONE of *Euclid,* was half a major tone less than the minor fourth, or $4th-\frac{1}{2}T$, $=\frac{1}{2}T+t+S$; its ratio is $3^2\div 8\sqrt{2}$, $=202.003931\Sigma+4f+17m$, or $202\Sigma+4f+17\frac{1}{2}m$, and its log. $=.9006375,2462$: it is $=\frac{1}{2}VIII-T$, $=.380076\times VIII$, $=18.41741\times C$.

DITONE, *Double Greater,* (4T) or four major tones, has a ratio $\frac{4096}{6561}$, $=416\Sigma+8f+36m$; it is the SUPERFLUOUS *Fifth* of Bemetzrieder. See that article.

DITONE, *Greatest,* or Ditonus of Holder and others, (2T) or two major tones, has a ratio $\frac{64}{81}$, $=208\Sigma+4f+18m$; it is the *Major* THIRD acute, or COMMA-*redundant,* which see.

DITONE, least of Holder, (2t) or two minor tones, has a ratio $\frac{81}{100}$, $=186\Sigma+4f+16m$: it is the *Major* THIRD grave, or *comma-deficient,* which see.

DITONE, *Semi,* or Sesquitone, (3d) is the least of the concords, if we except the unison, and is said to have been unknown to the ancients before Ptolemy's time; its ratio is $\frac{5}{6}$, $=161\Sigma+3f+14m$. See THIRD *Minor.*

DIU, is the name of an island in the Indian Sea, on the southern coast of Guzzerat. It is about two miles distant from Diu head, the southernmost part of the continent; and is about $6\frac{1}{4}$ miles long from east to west, and $1\frac{1}{2}$ broad from north to south. The channel which separates the island from the mainland, can be navigated only by fishing boats at half tide; and at the western entrance, which is defended by a square fort, there is only four or five feet at low water on the bar.

The island abounds with cattle, poultry, fish, and all sorts of provisions, which are cheaper here than at any of the English stations. There is, however, little fruit, and few vegetables.

The town of Diu is reckoned one of the best built, and one of the strongest cities in India. The streets are extremely narrow, but are kept very clean. The houses within the walls are of free-stone, and some of them, inhabited by Banians, are four or five stories high. The town contains several churches and convents. The castle of Diu is defended with more than 100 pieces of mounted cannon, several of which are of brass; and from the castle there extends a wall, with half-moon towers at equal intervals, and encircling the whole town. The sea gate and the land gate are always shut at sun-set. Opposite to the custom-house is a flight of stone steps, which form the landing place, and here are many shops and warehouses. Vegetables are brought to Diu from the mainland in great abundance; but beef is procured clandestinely, as the principal merchants are Hindoos. The water on the island is brackish. The rain water is kept in large reservoirs, and will last from one season to another. It is conveyed to the wharf in a canal, and delivered to the boats from a cock. Within 500 yards of the east side of the castle, there is water sufficient for a 74 gun ship.

In consequence of the bad conduct of the Portuguese, the immense trade which was formerly carried on at Diu has been transferred to Surat and other adjacent places. Tavernier, in his *Observations sur le Commerce des Indes,* considers Diu as one of the finest stations in the East for a great commercial establishment, from the safety of its harbour, the excellence of its water, the extraordinary quantity which it affords of all sorts of refreshments, and from its proximity to Surat, which can be reached in four or five days.

At Nowabunder, about five miles to the east of Diu, there is a nest of pirates, who keep their vessels in a small creek, protected by a little fort. They, however, spare all boats under Portuguese colours.

In the year 1509, when Albuquerque, at the head of the Portuguese, first visited Diu, he described the city as a grand and spacious place, girt with strong walls and lofty towers, all handsomely built and well laid out, like towns in Portugal. He attacked the shipping in the harbour, amounting to 200 sail, and took or sunk the greater part of them. Albuquerque, however, was induced to abandon his plan of attacking Diu; and having made an advantageous peace, he returned southward. After many attempts to get a fort erected in Diu, the Portuguese at last obtained permission, in 1534, from Badur, King of Cambaye, and they completed it in the short space of 49 days, and mounted 60 pieces of cannon upon the ramparts. Badur, however, repented of his concession, and began to build a wall or fortification between the fort and the city, which he was obliged to give up after strong remonstrances from the Portuguese.

In the year 1537, Badur made a treacherous attack upon Diu, slew De Sousa, the commandant of the fort, during a friendly interview, but lost his own life in the affray which ensued. The town of Diu was immediately surrendered to the Portuguese. They found only 200,000 pardaos (L.37,500 sterling), but the quantity of ammunition was immense. They obtained a prodigious number of brass cannon, among which were three basilisks of enormous size, one of which was sent by De Cuna as a curiosity to Lisbon, and was placed in the castle of St Julien, at the mouth of the Tagus, where it is known by the name of the great gun of Diu.

In the year 1538, the Turks, aided by the king of Guzzerat, made a desperate attempt upon Diu; but the Governor Silveira, conducted the defence in a stile of bravery and skill, which has perhaps never been surpassed in the annals of war. The acts of heroism and personal valour which were displayed during the siege, both by the men and the women of the garrison, would give splendour to the brightest page of history. The following account of this event is too interesting to require any apology:—"Hearing that the Turkish fleet was approaching, Sylveira sent immediate notice of it to Nuno de Cuna, who prepared with great diligence to go in person to relieve Diu. Michael Vas was sent to sea by Sylveira to look out for the enemy, and falling in with their fleet, came so near, on purpose to examine their force, that several of their shot reached his vessel. He got off however, and carried the news to the governor of Goa. The Turkish fleet came at length to anchor in the port of Diu, where it was formidable not only to the small Portuguese garrison in the fort, but to the Moors even who had long expected their arrival. Next day Solyman landed 600 well armed janizaries, who immediately entered the city and behaved with much insolence. Drawing near the fort, they killed six Portuguese; but 300 musqueteers attacked them from the fort, and drove them away with the loss of 50 men. In consequence of a storm, Solyman was obliged to remove his fleet to Madrefavat, as a safer harbour, where he remained 20 days, during which time Sylveira was diligently occupied in strengthening the fortifications of the castle, planting his artillery on the ramparts, and assigning every one his proper post for the ensuing siege. At the same time, the Turks assisted by Zofar, (one of the retinue of Badur who escaped from the affray of 1537,) commenced operations against the fort, by constructing batteries, and endeavouring to ruin the defences of a bulwark at the entrance of the harbour, which they battered with their cannon. With this view, likewise, they built a wooden castle on a large bark, which they filled with combustibles, meaning to send it against the bulwark to set it on fire. But Francisco de Gouvea, who commanded the small naval force then at Diu, went against this floating castle under night, and contrived to destroy it by fire. At this time, likewise, some relief was sent to the fort by Nuno de Cuna, and the garrison was much elated by the assurance of his intention of coming speedily in person to raise the siege.

Returning from Madrefavat, Solyman commenced a heavy fire from his ships against the sea bulwark in which Francisco de Gouvea commanded, but was so well answered, both from that work and the tower of St Thomas, that one of his gallies was sunk and most of her men drowned. The greatest harm suffered at this time by the Portuguese was from the bursting of some of their own cannon, by which several men were killed. Two brothers only were slain by the fire of the Turks. Zofar now so furiously battered the bulwark in which Pacheco commanded, that it became altogether indefensible, on which 700 janizaries assaulted it, and set up their colours on its ruined walls; but the Portuguese rallied and dislodged them, killing an hundred and fifty of the enemy. The assault of this bulwark was continued a whole day, and at night the enemy were forced to retreat with much loss. Next day Pacheco deeming it impossible to resist, surrendered upon promise of life and liberty to himself and his men. Solyman did not perform the latter stipulation, but he granted their lives for the present, and clothed them in Turkish habits. By one of these prisoners, Solyman sent a summons to Sylveira to surrender, but the proposal was treated with contempt. Solyman now planted his artillery against the fort, having, among other cannon, nine pieces of vast size, which carried balls of ninety pounds weight. His artillery in all exceeded 130 pieces of different sizes, and his batteries were continually guarded by 2000 Turks. This formidable train began to play against the castle on the 4th of October 1538, and continued without cessation for 20 days, doing great injury to the defences of the fort, which could hardly do any mischief in return to the besiegers, neither could the garrison repair sufficiently the most dangerous breaches, though they used every possible exertion for that purpose. On the sixth day after the commencement of this violent cannonade, perceiving that the bulwark commanded by Gaspar de Sousa was much damaged, the Turks endeavoured to carry it by assault, but were repulsed with much slaughter, two only of the defenders being slain. Every day there were assaults by the besiegers, or sallies by the garrison. In one of these, Gonzalo Falcam lost his head; and Juan de Fonseca, being disabled by a severe wound of his right arm, continued to wield his lance with his left as if he had received no hurt. A youth of only nineteen years old, named Joam Gallego, pursued a Moor into the sea and slew him, and afterwards walked back deliberately to the fort through showers of balls and bullets. Many singular acts of valour were performed during this memorable siege.

At length many brave officers and men of the besiegers were slain, powder began to wax short, and provisions shorter. The relief expected from Non Garcia Noronha, now come out as viceroy of India, was long in making its appearance. The remaining garrison was much weakened by a swelling in their gums, accompanied by their teeth becoming so loose that they were unable to eat what little food remained in the stores. Yet the brave garrison continued to fight in defence of their post, as if even misery and famine were unable to conquer them. Even the women in the fort exerted themselves like heroines. Donna Isabella de Vega, the wife of Manuel de Vasconcelles, had been urged by her husband to go to her father Francisco Ferram at Goa, lest the fort might be taken and she might fall into the hands of the Turks; but she refused to leave him. During the distress of the garrison, as many of the men were obliged to work in repairing the works, this bold-spirited lady called together all the women who were in the fort, and exhorted them to undertake this labour, as by that means all the men would be enabled to stand to their arms. The women consented to this proposal, and continued for the remainder of the siege to perform this duty. She was even outdone by Ann Fernandez, the wife of a physician, who used to visit the most dangerous posts by night, and even appeared at the assault to encourage the soldiers. Her son happening to be slain in one of the attacks, she immediately drew away his body, and returned to the place of danger, and when the fight ended she went and buried her son.

Perceiving that the Turks were undermining the bulwark which he commanded, Gasper de Sousa made a sally with seventy men to prevent that work, and made a great slaughter of the enemy. When retreating he missed two of his men, and returned to rescue them; but, being surrounded by the enemy, they cut the tendons of his hams, after which he fought upon his knees till he was overpowered and slain. The mine was countermined; but the continual labour to which the besieged were subjected became insupportable, and they were utterly unable to repair the many breaches in their works. At this conjuncture, four vessels arrived from the viceroy Don Garcia, and landed only a reinforcement of twenty men. Solyman was much concerned at this relief though small, and was astonished that the fort should hold out against so many assaults, more especially as Zofar had assured him he might carry it in two. At the beginning of the siege the garrison consisted of 600 men, many of whom were slain, and several of the cannon belonging to the fort had burst; yet Solyman began to lose confidence, and looked anxiously to the sea, fearful of the Portuguese fleet which he had learnt was coming against him. This induced him to press the siege more vigorously, especially against the sea bulwark where Antonio de Sousa commanded, which was furiously attacked by fifty barks, two of which were sunk by the Portuguese cannon. The Turks made several attempts to scale this bulwark, in all of which they were repulsed with great slaughter, yet returned repeatedly to the charge with similar bad fortune. Sousa sent off his wounded men from the rampart to have their wounds dressed. Among these was a person named Fernando Ponteado, who, waiting his turn, heard the noise of a fresh assault, and, forgetting the dressing, ran immediately to his post, where he received a fresh wound. Going back to get dressed, a third assault recalled him before the surgeon had time to attend to his wants, and he was a third time wounded, and at length returned to get all his three wounds dressed at once.

By this time, out of the original garrison of 600 men, only 250 remained that were able to stand to their arms. Solyman was almost in despair of success, yet resolved to make a desperate effort to carry the place. In hopes of putting Sylveira off his guard, and to take the place by surprise, he sent twelve of his gallies to sea, as if he meant to raise the siege; but Sylveira was not to be lulled into security, and continued to exert the utmost vigilance to provide against every danger. One night some noise was heard at the foot of the sea-wall of the castle, where it appeared that the enemy were applying great numbers of scaling ladders. Every effort was made to oppose them during the darkness of the night, and when morning broke, the place was seen beset all round by at least 14,000 men. The cannon of the fort was immediately directed against the assailants, and the garrison mounted the walls in every part, but chiefly near the governor's house, where the defences were weakest, but where Sylveira had placed such people as he could most rely upon. Being repulsed from thence with great slaughter, the enemy made an attempt on an adjoining bulwark, where Gouvea commanded, and poured in prodigious showers of bullets and arrows. Fourteen gallies came up against this bulwark, which they battered with their cannon; but Gouvea obliged them to draw off, having sunk two of the gallies, and killed many of their crews. At length 200 Turks forced their way into the bulwark, and planted their colours on its rampart. Scarcely thirty Portuguese remained to oppose them, yet they charged the enemy with great fury, who were so thick that every shot told, and they were driven out with much loss. Fresh men succeeded and regained the bulwark, on which they planted four standards. Many of the Portuguese, who were wounded and burnt by the fire-works of the enemy, ran and dipped themselves in jars of salt water, where, seeking ease, they perished in dreadful torment.

Sylveira went continually from place to place, encouraging all to do their duty manfully, and supplying reinforcements where they were most needed. The enemy had much the better in the second assault on the bulwark commanded by Gouvea, on which several gentlemen rushed upon them. At this time one Joam Rodrigues, a strong man of great bravery, ran forward with a barrel of powder on his shoulder, calling out to clear the way, as he carried his own death and that of many. He threw the barrel among the enemy, which exploded, and blew up above 100 of them; yet Rodrigues came off unhurt, and performed other memorable deeds, so that he merited the highest honours and rewards of those that were gained in this siege. By other fire-works, the four ensigns who set up the colours were burnt to death, and two others who went to succeed them were slain. Being again driven from the bulwark, the enemy made a third assault: But their commander being slain, who was son-in-law to Khojah Zofar, his men were dismayed and took to flight. These reiterated assaults lasted four hours, during which a small number of exhausted Portuguese had to withstand vast numbers of fresh enemies. At length, having 500 men slain and 1000 wounded, the enemy retired; while on the side of the Portuguese 14 were killed, and 200 were disabled from wounds. Only 40 remained who were able to wield their arms, insomuch that no hope remained of being able to withstand a fresh attack. The walls were shattered and ruined in every part: No powder remained: In fact, nothing was left but the invincible courage of Sylveira, who still encouraged the remnant of his brave garrison to persist in their defence. Not knowing the desperate state to which the fort was reduced, and dismayed by the bad success of all his efforts, Solyman raised the siege, and set sail with all his fleet on the 5th of November."

With the exception of another unsuccessful attempt in 1545, the Portuguese enjoyed the peaceful possession of Diu till 1670, when the Muscat Arabs took the city by surprise, and filled three vessels with the immense plunder which they collected. By mounting some cannon on a church, they attempted to destroy the fort; but though the Portuguese were prevented by the priests from firing at the church, the Arabs were unable to make any impression. Having become negligent and oversecure, the Portuguese took advantage of it; and sallying from the castle, they slew 1000 Arabs, and forced the remainder to abandon the city, and seek for shelter in their vessels. Since that time, Diu has never recovered from the evils which the Arabs inflicted upon it.

The population of Diu is about 40,000, only 200 of whom are Portuguese, the rest being Banians, Persees, and Moors. The position of Diu Head is in East Long. 71° 7′, and North Lat. 20° 42′. See Manuel de Faria's *Asia Portuguesa*, a translation of which will be found in Astley's *Collection of Voyages and Travels*, vol. i. p. 58; and in Kerr's *Collection of Voyages and Travels*, vol. vi. p. 69. See also Milburn's *Oriental Commerce*, vol. i. p. 151. (*j*)

DIVERGENCY of *Tune*. M. Huygens and M. Sauveur have both treated on the deviation from the pitch first assumed, which singers experience in singing certain passages or successions of intervals in perfect tune; owing to the want of that necessary or exact connection between melody and harmony, which the modern theories of music have assumed. Mr Maxwell, in his "Essay upon Tune," has considered the causes of this divergency, and has directed violin performers how to avoid its effects, in passages which Composers, unacquainted with this theory, have left in their works. Mr Liston has shewn, in his "Essay on perfect Intonation," how this divergency may be corrected in an almost insensible manner, or avoided, or managed at pleasure, by the peformers on his euharmonic organ, by what he calls ENHARMONIC *Changes*, which see.

DIVERS. See DIVING.

DIVICOTTA, or DEVYCOTTA, is the name of a fort in Hindostan, situated on a small island within the entrance of Coleroon river. It is built of brick, and is very strong. It was taken in 1749 by the English under Major Lawrence, from the rajah of Tanjore. As there is sufficient water for large ships within the bar, the East India Company proposed to form this place into a harbour, and with this view they obtained from the rajah the cession of a district. This plan, however, has been long ago abandoned. The four famous pagodas, called the Chalanbaran Pagodas, are to be seen up the country. North Lat. 11° 22′. See Milburn's *Oriental Commerce*, vol. i. (*j*)

DIVIDEND has, in arithmetic, the general signification of "any number given to be divided;" in commerce, it has two significations, of very frequent occurrence, viz. the "share obtained by a creditor out of a bankrupt estate," and the "money paid as the interest or return of capital invested in a public fund." In the latter, the times of payment are generally half yearly; and though, strictly speaking, the amount in all joint stock companies ought to fluctuate with the profits of the concern, it has been found more advisable to adopt an average rate, and to adhere to it as nearly as possible, for the sake of preventing uncertainty and agitation to the body of stock-holders. The West India Dock, and London Dock Companies, for example, have adhered, with little variation, to the dividends with which they respectively set out. The India Company, having at one time raised their dividend to 10 per cent. have thought proper to continue it at that rate; and a similar rule has been adopted by the Bank of England for a number of years, subject, however, to the prospect of reduction on the resumption of cash payments. But of all dividends, the most familiar to the public at large are the payments made by government to stock-holders, in discharge of the interest of the national debt. These take place half yearly, and principally in the months of January and July, April and October. It is customary to begin by making the payments to the London bankers, who receive very large sums as agents for stock-holders living at a distance from the Bank. The issue to the bankers has the effect of throwing a great deal of money directly into circulation; after which, in the course of a few days, payments are made to all private individuals, who choose to call at the Bank for the half year's interest of stock belonging either to themselves, or to those for whom they are empowered to act. The books containing the names of the stock-holders are numerous, and, on entering the offices at the Bank, the eye is directed to the proper clerks by the initial letters being painted conspicuously against the wall. Before issuing the dividends, it is necessary to take some time to post the bank-books in the names of the last holders of the stock, as changes are perpetually occurring in a property so easily transferable. During this interval, the transfer books are said to be "shut;" that is, no transfers can be regularly entered in them, till after payment of the dividends.

In consequence of deaths and absence from the country, there occur frequent omissions in calling for accrued dividends. The amount thus remaining unpaid, having, about the year 1790, become very considerable, it was determined to publish the names of the proprietors of the stock in question, and afterwards to appropriate the balance to the public use, until it should be called for by the parties entitled to it. The sum thus taken over by government was at first £376,739; and, in 1808, a farther sum of half a million was, in like manner, paid into the Exchequer by the Bank; a provision, however, being made, that the balance of unclaimed dividends remaining in the hands of the Bank, should not at any time be reduced below £100,000.

It was in the beginning of the present war, that the property tax was first deducted from the stock-holder, before making payment of the dividend. An idea was at one time general, that the interest of all money lent to government, should be paid free of any tax or deduction whatever; but the ardour of the public for war against Bonaparte, enabled ministers to act on a different interpretation of the law; so that the only dividends exempt from the operation of the property tax, are those which are payable to foreigners. Attempts have even been made in the House of Commons, to procure an act subjecting the latter, like ourselves, to a deduction on the score of property tax; but government have thought it advisable to wave this limited advantage, in consideration of the impolicy of discouraging the investment of foreign capital in our funds. (*x*)

GENERAL EXPLANATION

OF THE

PLATES BELONGING TO VOLUME SEVENTH

OF THE

EDINBURGH ENCYCLOPÆDIA.

PLATE CCIII.

Fig. 1. Nautilus Beccarii. *Magnified.* A spiral Shell, with the cavity divided into chambers.
a, One of the chambers.
b, The partition.

Fig. 2. Helix Paludosa. A spiral Shell, with an undivided or unilocular cavity.

Fig. 3. Orthocera Recta. *Magnified.*
a, The outside.
b, a section, which exhibits the chambers.

Fig. 4. Dentalium Gadus. *Magnified.* An unilocular tubular Shell.

Fig. 5. Odostomia Muscorum. *Mag.* Spires *dextral.*

Fig. 6. Odostomia Laminata. Spires *sinistral.*

Fig. 7. Murex Corneus. Divided, in order to exhibit the *pillar* round which the spires revolve.
a, The pillar.
b, The mouth.
c, The canal in which the cavity of the mouth terminates.

Fig. 8. Planorbis Complanatus. Divided, the spires lateral, and destitute of a pillar.

Fig. 9. Helix Margarita.
a, The operculum or lid.

Fig. 10. Turbo Elegans.
a, The operculum rayed.

Fig. 11. Turbo Disjunctus.
a, Spires very distinctly separated.

Fig. 12. Buccinum Reticulatum.
a, Outer lip denticulated.

Fig. 13. Voluta Triplicata.
a, The pillar lip plaited.

Fig. 14. Helix Lævigata. With the epidermis.

Fig. 15. —— ———. Epidermis removed.

Fig. 16. Nerita Glaucina.
a, The pillar cavity.

Fig. 17. Nerita Canrena.
a, The pillar cavity grooved.

Fig. 18. Pectunculus Pilosus.
a, The crenulated margin.
b, The teeth of the hinge.
c, The ligament.
d, The beak.

Fig. 19. Venus Decussata.
a, The broad border line approaching the middle of the Shell.
b, The ligament.
cc, The cicatrix.

Fig. 20. Venus Pullastra.
a, The fold of the border line, nearer to the margin than in Venus Decussata.
b, The ligament.
c, The cicatrix.

Fig. 21. Solen Marginatus.

a, The external ligament.
b, the gape.

Fig. 22. Mytilus Modiolus. Young shell.
a, The longitudinal furrow of the hinge destitute of teeth.

Fig. 23. Tellina Radula.
a, The base.
b, The anterior margin.
c, Posterior margin.
d, Superior margin.
f, The right valve.
g, The left valve.

Fig. 24. Lepas Anatifera.
a, The peduncle.
b, The connecting ligament.
c, The base.

Fig. 25. Balanus Punctatus. An articulated Shell.
a, The accessory valves.

PLATE CCIV.

Fig. 1. Patella Cœrulea.
a, The young shell.
Fig. 2. ——— Elongata.
Fig. 3. ——— Elliptica.
Fig. 4. ——— Distorta.
Fig. 5. ——— Zetlandica.
Fig. 6. ——— Marginata.
Fig. 7. Cæcum Glabrum.
Fig. 8. Serpula Serrulata.
Fig. 9. ——— Tubularia.
Fig. 10. Lagena Globosa.
Fig. 11. ——— Perlucida.
Fig. 12. ——— Urnæ.
Fig. 13. Spirorbis Carinatus.

PLATE CCV.

Fig. 1. Spirorbis Heterostrophu
Fig. 2. ——— Minutus.
Fig. 3. ——— Conicus.
Fig. 4. ——— Lucidus.
Fig. 5. Murex Rufus.
Fig. 6. Turbo Auricularia.
Fig. 7. Helix Hortensis, with the margin of the mouth white.
Fig. 8. Serpula recta anfractibus tribus contiguis regulariter involutis of Mr Walker, *Test. Min. Rar.* tab. 1. fig. 11.
Fig. 9. Serpula recta umbilico pervio anfractu apicis unico involuto of Mr Walker, *Test. Min. Rar.* tab. 1. fig. 12.
Fig. 10. Turbo Elegantissimus. Shell glossy, white, with thirteen spires, longitudinally ribbed; aperture suborbicular; inner lip a little reflected; length scarcely three-eighths. Not uncommon in England; rare in Scotland.
Fig. 11. Miliola Lactea. Shell pellucid, smooth, thin, egg-shaped, with milky veins. In England and Scotland rare.
Fig. 12. Pecten Subauricula.
Fig. 13. Mactra Solida.
Fig. 14. ——— Truncata.
Fig. 15. ——— Subtruncata.

PLATE CCVI.

Fig. 1. Venus Reflexa.
Fig. 2. Terebratula Vitrea.
Fig. 3. Pinna Ingens.
a, The byssus.
Fig. 4. Turbo Scalaris, or Wentle-trap, of an uncommon size, and great value. From the Museum of Mr Bullock.

PLATE CCVII.

Contains Diagrams for illustrating the article CONIC SECTIONS.

PLATE CCVIII.

Contains Diagrams for illustrating the article CONIC SECTIONS.

PLATE CCIX.

Contains Diagrams for illustrating the article CONIC SECTIONS.

PLATE CCX.

Contains Diagrams for illustrating the article CONIC SECTIONS.

PLATE CCXI.

Contains Diagrams for illustrating the article CONIC SECTIONS.

PLATE CCXII.

Fig. 1. Represents the Roller Gin, on a new construction for separating the gins, or seeds, from the cotton.
Fig. 2. Is a representation of the Saw Gin, for the same purpose.
Fig. 3. Represents the Centrifugal Cotton Picker, for cleaning cotton.
Fig 4. Represents an improved Batting Machine, for preparing the cotton.
Fig. 5. Is a horizontal plan of a New Diagonal Mule for spinning cotton, invented by Mr John Duncan of Glasgow.
Fig. 6. Is a Perspective Representation of the same Machine.

PLATE CCXIII.

Fig. 1. Shews part of the Boards of a Pair of Hand-cards.
Fig. 2. Shews the Form of one of the Wires stuck through the leather.
Fig. 3. Is a Vertical Section of the Breaker used in carding cotton.
Fig. 4. No. 1. and 2. Represent a Front View and Plan of the Taker-off and the Finisher.

Fig. 5. Is a Vertical Section of the Finisher.
Fig. 6. Represents the Fast and Loose Pullies for throwing into action and disengaging the machinery.
Fig. 7. Represents a Pair of Rollers for drawing the cotton.
Fig. 8. Represents one Head of a Drawing Frame.

PLATE CCXIV.

Fig. 1. Represents one head of a Drawing Frame.
Fig. 2. Is a view of the Can Roving Frame.
Fig. 3. Represents the Jack Frame.
Fig. 4. Is a view of the Spindle and Flyer Roving Frame.
Fig. 5. Is a Profile of one head of the Water Spinning Frame.
Fig. 6. Represents another Spinning Frame, called the Throstle.
Fig. 7. Shews the Reel for winding up the Cotton into Hanks, &c.
Fig. 8. Represents the method of Mule Spinning.

PLATE CCXV.

Fig. 1. Is a representation of one of the Hydrostatic Cranes, invented by Mr Bramah.
Fig. 2. Represents another of Mr Bramah's Hydrostatic Cranes, for raising weights to a small height.
Fig. 3. Is a view of the Safety Valve of the Crane.
Fig. 4. Represents the inclined Walking Wheel Crane, invented by Mr James White of Chevening, in Kent.
Fig. 5. Is a view of the New Crane, invented by Mr Gilbert Gilpin.
Figs. 6, 7, and 8. Contain a separate representation of some of the most important parts of Mr Gilpin's Crane.
Fig. 9. Represents Mr Kier's Moveable Crane, which was employed in the erection of Ramsgate Pier.
Fig. 10, and 11. Contain two views of the Lowering Cylinder, invented by Mr Hardie.

PLATE CCXVI.

Fig. 1. Represents a small Crane, made of cast iron.
Fig. 2. Is a similar Crane, but of greater strength and power.
Fig. 3, and 4. Are side and front elevations of another iron Crane.
Fig. 5. Is another iron Crane of a different construction.
Fig. 6. Represents an iron Crane suitable for an iron foundery.

PLATE CCXVII.

Fig. 1, 2, and 3. Represent a side and back view of the Crane erected on the Grand Junction Canal at Paddington.
Fig. 4. Shews a transverse view of the Crane used for constructing the Breakwater at Aberdeen harbour.
Fig. 5. Is a Longitudinal view of the Crane.
Fig. 6. Is a plan of the Crane with Waggons and Railways.
Fig. 7. Is an enlarged view of the Sliding Carriage.
Fig. 8. Is a Plan of the Sliding Carriage.

PLATE CCXVIII.

Fig. 1. Represents the Facial Angle of Camper in the Skull of a Negro.
Fig. 2. Is the Inferior Basifacial line of Dr Barclay, on the Skull of the *Babirossa Vulgaris.*
Fig. 3. Is the Skull of a Negress from the coast of Guinea.
Fig. 4. Represents the Skull of a Georgian Female.
Fig. 5. Is the Skull of a Tungoose.
Fig. 6. Represents the Craniometer invented by Dr Barclay, for measuring the various diameters of the Cranium.
Fig. 7. Shews the Craniometer invented by Dr W. E. Leach of the British Museum, for measuring the Inferior Basifacial angle of Dr Barclay.

PLATE CCXIX.

Figs. 1, and 2. Represent a Profile elevation of the Common Linau, or Gauze Loom.
Figs. 3, and 4. Represent the Machinery of Crossed Texture, where the twist is carried one half farther than in common linau or gauze, that is of open and crossed catgut.
Fig. 5. and 6. Represent the open and crossed Whip-net.
Fig. 7. Represents the Patent Net open.
Fig. 8. Shews the Patent Net crossed and finished.
Fig. 9. Is a representation of the Patent Draw Loom, described under the Article CLOTH MANUFACTURE, p. 690.

PLATE CCXX.

Figs. 1, 2, and 3. Represent the Apparatus for Weaving the Russia Table Rubber.
Fig 1. Is the Front Elevation of the Loom.
Fig. 2. Is the Profile Elevation.
Fig. 3. Is a general Plan for representing each successive stage of the Operation of the Lams.
Figs. 4, 5, 6, and 7. Represent Looms for Weaving goods called Lappets.

PLATE CCXXI.

Contains a representation of Crustaceous Animals.
Fig. 1. Limulus Polyphemus.
Fig. 2. Cypris Reniformis.
Fig. 3. Pinnotheres Pisum.
Fig. 4. Leptopodia Phalangium.
Fig. 5. Crangon Vulgaris.
Fig. 6. Orchestia Littorea.
Fig. 7. Idotea Entomon.
Fig. 8. Ligia Oceanica.

Fig. 9. Julus, an exotic species, to shew the character of the genus.
Fig. 10. Scolopendra of that family with alternate joints.
Fig. 11. Pycnogonum Balænarum.
Fig. 12. Aranea Parietina.

PLATE CCXXII.

Contains twenty-one Diagrams for illustrating the Mathematical Theory of Crystals.

PLATE CCXXIII.

Contains thirty-eight Diagrams for illustrating the Mathematical Theory of Crystals.
Fig. 34. Represents the Goniometer used by Romé de Lisle and Hauy for Measuring the Angles of crystals.

PLATE CCXXIV.

Fig. 1. Represents the Reflective Goniometer invented by Dr Wollaston for Measuring the Angles of Crystals.
Fig. 2. Represents the Reflecting Goniometer invented by Dr Brewster.
Fig. 3—25. Are Diagrams for illustrating the Mathematical Theory of Crystals.

PLATE CCXXV.

Fig. 1—8. Are Diagrams for illustrating the Mathematical Theory of Crystals.
Fig. 9. Is the primitive form of Leucite or Amphigene.
Fig. 10. Analcime, or Cubizite.
Fig. 11. Sulphate of Magnesia.
Fig. 12. Vesuvian, or Idocrase.
Fig. 13. Meionite.
Fig. 14. Mesotype, or Radiated Zeolite.
Fig. 15. *Id.*
Fig. 16. Chrysoberyl, or Cymophane.
Fig. 17, 18. Chrysolite, or Peridot.
Fig. 19. Stilbite, or Foliated Zeolite.
Fig. 20. Prehnite.
Fig. 21. Wolfram.
Fig. 22. Sulphate of Barytes.
Fig. 23. Sulphate of Strontian.
Fig. 24. Granatite, or Staurotide.
Fig. 25. Talc.
Fig. 26. Arsenical Pyrites, or Mispickel.
Fig. 27. Gypsum, or Sulphate of Lime.

PLATE CCXXVI.

Fig. 1, 2. Pistazite Epidote, or Zoisite.
Fig. 3. Axinite, or Thummerstone.
Fig. 4. Amphibole, Hornblende, Actinolyte, Grammatite, and Tremolite.
Fig. 5. Augite or Pyroxene, Coccolite, Diopside, and Salite.
Fig. 6. Felspar.
Fig. 7. Cyanite, or Disthene.
Fig. 8, 9. Sulphate of Copper.
Fig. 10. Carbonate of Lime, Equiaxe of Hauy.
Fig. 11. Ditto, Inverse of Hauy.
Fig. 12. Ditto, Metastatic of Hauy.
Fig. 13. Ditto, Contrasting of Hauy.
Fig. 14. Ditto, Regular Six-sided Prism.
Fig. 15. Quartz.
Fig. 16. Tourmaline, or Schorle.
Fig. 17. Oligiste, or Glance Iron ore.
Fig. 18. Apatite.
Fig. 19. Nepheline, or Sommite.
Fig. 20. Garnet.
Fig. 21. Diamond.
Fig. 22. Topaz.
Fig. 23. Calamine.
Fig. 24, 25. Zircon.
Fig. 26. Harmotome, Cross stone, or Staurolite.
Fig. 27, 28. Molybdate of Lead.
Fig. 29. Common form of Anatose, or Octahedrite.
Fig. 30. Primitive form of Carbonate of Soda.
Fig. 31. Common form of Carbonate of Soda.

PLATE CCXXVII.

Fig. 1. Is a perspective representation of a Draw-loom, adapted for Damask Tweeling.
Fig. 2—16. Are various Diagrams for illustrating the Theory of Curve Lines and Surfaces.

PLATE CCXXVIII.

Fig. 1. Is the representation of an Ancient Dial found in 1741, in the Ruins of a Roman House in Tusculum, and supposed to have belonged to Cicero.
Fig. 2. Is a very curious Portable and Ancient Dial, dug out of the ruins of Portici in 1755.
Fig. 3. Is a Diagram for illustrating the general principles of Dialling.
Fig. 4 and 5. Shew the method of Tracing a Meridian Line from Three Shadows of a Stile.
Fig. 6. Shews the method of transferring the Meridian Line to any place.
Fig. 7. Represents an Universal Equinoctial Dial.
Fig. 8. Is a perspective representation of an Horizontal Dial.
Fig. 9. Shews the method of constructing a Horizontal Dial.
Fig. 10. and 11. Shew a geometrical method of constructing Horizontal Dials.
Fig. 12. Illustrates another geometrical method of constructing Horizontal Dials.
Fig. 13. Shews the method of constructing Dialling Scales.
Fig. 14. Shews the method of constructing Horizontal Dials by Dialling Scales.
Fig. 15. Points out the method of constructing Horizontal Dials, by means of a Globe.
Fig. 16. Is a Vertical South Dial.
Fig. 17. Is a Vertical North Dial.
Fig. 18. Diagram for explaining the nature of Vertical East and West Dials.

PLATE CCXXIX.

Fig. 1. Represents an East Dial.
Fig. 2. Represents a West Dial.

Fig. 3. Is the form of the Stile for East and West Dials.
Fig. 4. Represents a Polar Dial.
Fig. 6. Is a Diagram for explaining Vertical Declining Dials.
Fig. 6. Represents a Vertical South Dial declining to the West.
Fig. 7. Represents a Vertical South Dial declining to the East.
Fig. 8. Is a Diagram shewing how to construct a Declining Dial, by considering it as a Horizontal Dial for some other place.
Fig. 9. Is a Diagram shewing how to find the Declination of a plane.
Fig. 10, 11. Are Diagrams explaining the theory of Inclining Dials.
Fig. 12. Represents an Inclining Dial.
Fig. 13, 14. Are Diagrams shewing how to find the path described on a plane by the extremity of a Shadow.
Fig. 15. Is a Diagram explaining the Retrogradation of the Shadow on particular Dials.
Fig. 16. Explains the theory of Dials with Variable Centres.
Fig. 17. Represents a Dial with a Variable Centre.

PLATE CCXXX.

Fig. 1. Shews the geometrical construction of an Analemmatic or Azimuth Dial.
Fig. 2. Represents a Dial which sets itself, being composed of an Analemmatic and a Horizontal Dial.
Fig. 3. Represents Lambert's Dial.
Fig. 4. Shews how to construct a Portable Dial on a Card.
Fig. 5. Represents a Portable Dial on a Card.
Fig. 6. Represents a Dial on the surface of a Cylinder.
Fig. 7. Shews how to construct the preceding Dial.
Fig. 8, 9, 10. Shew the construction of a Ring Dial.
Fig. 11, 12. Represent an Universal Dial on a Cross, and the method of constructing it.
Fi . 13. 14. Represent Ferguson's Universal Dial which shews the hour by the Terrestrial Globe and by several Gnomons at the same time.
Fig. 15. Represents a Vertical South Dial, with the Babylonian Hours.

END OF VOLUME SEVENTH.
